Abstract

The paper examines the levels and trends in access to education and educational outcomes across generations of Egyptian youth. Examination of three cohorts of individuals aged 21 to 24 (born between 1964 and 1967, 1974 and 1977, and 1982 and 1985) shows that access to education has substantially improved during the last three decades. Completion rates increased by more than 60 percent at the preparatory level and 70 percent at the secondary level and the college completion rate more than doubled. However, significant inequities remain in access to education and educational outcomes. The fraction of never enrolled among the cohorts is still large, affecting more girls than boys, more rural than urban areas, and more children of parents with lower level of education and in elementary occupations, such as subsistence agriculture. The analysis of test-scores

from the Trends in International Mathematics and Science Study (TIMSS) and national examinations shows that more than a quarter of learning outcome inequality is attributable to circumstances beyond the control of a student, such as parental education, socioeconomic background and place of birth. In Egypt, inequality of opportunity in learning outcomes emerges early and builds up progressively throughout the education levels. Access to higher education continues to remain significantly lower for children from rural areas and for those whose parents have a low level of education or are engaged in elementary occupations. Tracking into vocational and general secondary schools, which depends on a high-stakes national examination, and high and unequal levels of household expenditures in private tutoring substantially contribute to unequal learning outcomes.

This paper is a product of the Social Protection and Labor Global Practice Group. It is part of a larger effort by the World Bank to provide open access to its research and make a contribution to development policy discussions around the world. Policy Research Working Papers are also posted on the Web at <http://econ.worldbank.org>. The authors may be contacted at lersado@worldbank.org.

The Policy Research Working Paper Series disseminates the findings of work in progress to encourage the exchange of ideas about development issues. An objective of the series is to get the findings out quickly, even if the presentations are less than fully polished. The papers carry the names of the authors and should be cited accordingly. The findings, interpretations, and conclusions expressed in this paper are entirely those of the authors. They do not necessarily represent the views of the International Bank for Reconstruction and Development/World Bank and its affiliated organizations, or those of the Executive Directors of the World Bank or the governments they represent.

Egypt: Inequality of Opportunity in Education

1. Introduction and Motivation

The 2011 uprisings in Egypt and the wider Arab world have been at least in part fueled by lack of economic opportunities and apparent social injustice. Since then, the distribution of economic opportunities and how they are shaped by public policies have taken center stage. An effective delivery of education services and expanding opportunities in the labor market¹ may go a long way in addressing the demands of the citizens, particularly the youth, which epitomized the uprisings: bread, dignity, opportunity and social justice. While Egyptians have benefited from improved access to education in the last several decades, education system is facing several challenges and some of these may have contributed to the discontent of the youth. First, the expansion of schooling has been accompanied by limited improvements in labor market outcomes (e.g. Pritchett 1999). In addition to weak job creation and rigidities in the labor markets, the disappointing labor outcomes may have their origin in poor quality education and mismatch in the skills acquired and that demanded in the labor market.

Second, there is a widespread perception of injustice within the Egyptian society that the chances to acquire good education differ vastly among socioeconomic and geographic groups (e.g., Binzel, 2011). Several features of the Egyptian education system may have contributed to the perceived inequities. The distribution of public resources tends to be skewed towards higher education and youth from disadvantaged backgrounds have very little chance of availing themselves to benefit from such public outlays. For example, while overall public expenditures on education in the late 2000s was about 4%, which is lower than both the average for the middle East and North Africa (MNA) region (4.5%) and that of the OECD (4.7%), the ratio of spending per student in higher education relative to pre-university education, at 3.2, is almost three times that of the OECD countries (Assaad, 2010). Youth from most privileged backgrounds (such as those from urban areas,

¹ Campante and Chor (2012) argue that the mismatch between those educational gains and the lack of job opportunities contributed to the protests by decreasing the opportunity cost of time devoted to political activities

top wealth quintile, and parents with higher education) almost always attend university while those from most disadvantaged backgrounds (such as those from rural areas, lower wealth quintile, and less educated parents) have almost no chance of doing so.

Third, Egyptian pupils are tracked into general and vocational education at the senior secondary level, likely leading to divergence in educational and labor market outcomes. As the Egyptian education system relies on meritocratic selection into different education tracks, educational opportunities at the early stage could largely determine later education trajectories. Admission to general secondary and higher education institutions is based on performance in a high stakes national examination. A small minority of pupils, mainly from relatively better-off family backgrounds, meet the admission criteria, while a majority is tracked into vocational secondary schools ([Heyneman, 1997](#); [World Bank, 2007](#)). Private expenditures in tutoring play an important role in students' performance on national examinations.

Finally, existing empirical evidence shows large heterogeneity in schooling conditions for Egyptian youth with important implications on educational outcomes. In the early 1980s, [Loxley 1983](#) looked at the issue of the relative contribution of family and school inputs in learning and found that school resources do matter and help pupils from poorer backgrounds and compensate to some extent for the lack of family inputs. [Lloyd et al. \(2003\)](#) have used data from a survey of young people and the schools they attend in the late 1990s to document the effects of schools' inputs and environments on attainments. The study found that school conditions significantly affect schooling decisions.

This paper documents the level and evolution of inequities in access to education and educational achievements in Egypt. First, it analyzes the distribution of access to education and educational attainments, and the relationships between a set of circumstances, or characteristics determined at birth and lying outside a student's control, and educational outcomes. Second, the paper measures the inequalities in learning achievements and their evolution across educational levels and generations of Egyptian youth. For this, three main sources of data are used: (a) Egypt's

labor force surveys conducted in 1988, 1998 and 2006; (b) test-scores in Trends in International Mathematics and Science Study (TIMSS) in 2003 and 2007; and (c) national examination scores at completion of primary, preparatory and secondary education. Finally, the paper looks at the role of two potential factors of learning inequities: (a) the extent to which exam score differentials are associated with attendance of different school systems; and (b) the role of private expenditures in tutoring on learning outcomes.

The paper is structured as follows. Section 2 focuses on changes in educational attainments and their association with an individual background. Section 3 provides measures of the opportunity-shares of learning achievement inequalities. Section 4 provides empirical evidence on the contributions of attendance of schools from different systems and of private expenditures in tutoring to the formation of learning inequities. Section 5 concludes the paper.

2. Access to Education and Educational Attainment

Here we look at access to education by individuals from different socioeconomic and geographic backgrounds over the last two decades. We use data from three labor force surveys: the Egypt Labor Force Sample Survey (LFSS) of 1988, the Egypt Labor Market Survey (ELMS) of 1998, and the Egypt Labor Market Panel Survey (ELMPS) of 2006.² The surveys are representative of the total population and consist of about 28,000, 24,000, and 37,000 individuals, respectively. They are based on similar sampling design and questionnaires, ensuring data comparability. The surveys collected information on educational attainments, measured by completed levels of education and school enrollment, as well as on gender, region of birth, parents' educational attainments, and father's occupational status. The paper looks specifically at a subsample of young people aged 21-24 years, most of whom have already completed their education.³

Table 1 presents the completion rates at preparatory, secondary and college levels for 21-24

² The LFSS 1988 was conducted by the Central Agency for Public Mobilization and Statistics (CAPMAS). The ELMS 1998 and ELMPS 2006 were conducted by the Economic Research Forum (ERF) in cooperation with CAPMAS.

³ A small number are still enrolled in college but this is not a concern to the extent that they already attained some higher education.

year-olds in 1988, 1998 and 2006. The completion rates at preparatory level increased steadily from 43 to 69 percent and at secondary from 38 to 65 percent over the same period. Access to higher education increased substantially with completion rates increasing from 7 to 17 percent. Nevertheless, tracking into technical-vocational and general secondary schools remained high over the period. As a result, the rate of graduation from the vocational secondary schools increased faster (from 24 to 42 percent) than from the general secondary schools (from 19 to 27 percent).

Table 1: Completion rates of 21-24 year-olds by education level

	1988	1998	2006
Preparatory	0.434	0.527	0.692
Secondary	0.379	0.480	0.645
General secondary	0.194	0.167	0.269
College	0.0668	0.111	0.172

Source: 1988 LFSS; 1998 ELMS; and 2006 ELMPS. Sample: 21-24 year-olds

Table 2 presents probit model estimates of the relationship between educational attainment and circumstances beyond the control of an individual. The effects of circumstance variables on completion of preparatory, general secondary and college education are substantial. Other things being equal, girls are less likely to complete basic education over the entire period (with differentials of 2 in 1988 and 1998 and 4 points in 2006). However, gender gaps have decreased at general secondary and college levels. The disadvantage of girls has disappeared over the period and even been reversed at secondary levels with girls 3 percent more likely than boys to complete general secondary education in 2006. Similarly, the disadvantage of girls at higher education levels appears to have reversed with a 2 percent higher college completion rate in 2006.

The differentials between youth of different family backgrounds also tend to decrease over time. For instance, the differential associated with the agricultural (or elementary) occupation of a father (13 percentage points in 2006) declined by more than twice, as did the differential associated with parental education. Similarly, although youth born in rural Lower and Upper Egypt are much less likely to complete basic education (respectively 23 and 15 percentage points less in 2006,

compared to youth born in Cairo), the gaps between rural and urban areas have decreased somewhat over the period (although the progress is limited in Upper Egypt). Thus the expansion of enrollment at basic education seems to have benefited youth from disadvantaged backgrounds and rural areas.

However, the gaps associated with parental background and region of birth have not diminished at upper education levels, where completion rates have increased mostly for kids from more privileged backgrounds. At the general secondary level, youth born in rural Upper Egypt are 14 and 18 percentage points less likely to attain a general secondary education in 1988 and 2006, respectively. Youth whose father has an agricultural (or elementary) occupation seem to be at a higher disadvantage in 2006 than in 1988, with 9 percentage points lower likelihood to attain a general secondary degree. Finally, the differentials associated with mother's education persisted.

Similarly, at the college level, the differentials associated with region and family background persist and have even increased over the entire period. For instance, youth born in rural Upper Egypt are 11 percentage points less likely than those born in Great Cairo to attain a college education in 2006 (3 percentage points in 1988). Children of agricultural workers are 6 percentage points (4.5 percentage points in 1988) less likely than children of higher occupation fathers. Youth whose mothers are uneducated are 22 percentage points (11 percentage points in 1988) less likely than those whose mothers have attained secondary education. In general, while basic education has been democratized, barriers to access to general secondary and college education have remained for kids from disadvantaged backgrounds. This is a sign of the increased competition taking place for accessing general senior-secondary schools and universities.

Least and most advantaged groups

In addition to the descriptions given above, there are other informative ways to illustrate the stark disparities among circumstance groups. One way is to compare the characteristics of students belonging to the extremes of the distribution of educational achievements. **Table 3** describes the characteristics of the youth who did not complete basic education and of those who completed college education. Uneducated youth consist in more than 1,300,000 individuals aged 21-24 in 2006 (that number decreased only slightly from 1,500,000 in 1988), and the share of girls increased

among them to reach two-thirds for that year. They tend to be more concentrated in rural areas (more than 80 percent in 2006), are in great majority children of uneducated parents (more than 90 percent in any year), and children of agricultural (or elementary) workers (more than 60 percent in 2006). At the other end, college graduates vastly increased from about 220,000 individuals aged 21-24 in 1988 to more than 1,100,000 in 2006; girls became the majority of them (57 percent in 2006). While the share of college graduates in rural Lower Egypt increased, no increase was observed in rural Upper Egypt. The shares of individuals from more disadvantaged backgrounds diminished among college graduates. For instance the share of children from agricultural or elementary workers diminished from 46 to 26 percent, while the share of children of higher occupation fathers increased from 35 to 55 percent.

Population	1,492,612	953,225	1,345,590	220,180	496,557	1,089,725

Source: 1988 LFSS; 1998 ELMS; and 2006 ELMPS. Sample: 21-24 year-olds

Another way is to group students into least and most advantaged based on their individual circumstances. Here we define least advantaged youth as those with unfavorable circumstances, such as being born in rural areas, from uneducated parents, and having a father with elementary or

subsistence agricultural occupation. On the other hand, most advantaged youth are defined as those with favorable characteristics, namely being born in urban areas of the Greater Cairo, Alexandria, Suez, or Port Saïd, from parents with secondary or higher education, and having a father with higher occupational status (professional, manager, technician, or clerk). **Figure 1** shows the distribution of attainments for 21-24 year-olds for the least and most advantaged groups. The least advantaged account for 25 percent of the population of 21-24 year-olds in 1998 and 2006 (and slightly more, 27 percent, in 1988), while the most advantaged account for 3 percent of the population in 1998 and 2006 (and 2 percent in 1988).

Figure 1: Attainments among least and most advantaged groups

As expected, the prospects of the two groups are strikingly different: in 2006, only 5 percent of the least advantaged have attained a college education, 41 percent secondary, 13 percent primary, and 38 percent never attended school (Figure 1). On the contrary, 65 percent of the most advantaged have attained a college education, 29 percent secondary, and only 4 percent did not complete secondary education. However, there is evidence of democratization between 1988 and 1998: the share of never attenders decreased substantially from 67 to 38 percent among the least advantaged

and many of them were able to accessed basic education. The share of college graduates increased by 17 points among most advantaged, while there was no appreciable increase among the least advantaged.

Drop-out rate

A similar picture emerges when looking at the drop-out rate among those who participated in the 2007 TIMSS survey for 8th graders. Consider 15-19 year-olds in 2006, most out-of-school children actually never enrolled (about 13 percent of 15-19 year-olds in 2006) or dropped out after obtaining some vocational secondary education (15 percent). Drop-outs after primary (7 percent) or preparatory (4 percent) are less frequent. **Table 4** reports results from a partial correlations analysis of drop-out, i.e. probit estimates of the marginal effects of a set of circumstance variables for the same samples of 15-19 year-olds in 1988 and 2006. Girls have more often dropped out than boys, but the gap decreased from 23 to 8 percentage points between 1988 and 2006. While large geographic differentials persist in drop-out rate, there have been continuous improvements over the last two decades. Children born in rural Upper Egypt continue more likely to drop out than those born in any other region but the gap decreased from 21 to 9 percentage points, compared to Greater Cairo. However some gaps associated with family background have only slightly diminished, e.g. children with uneducated parents are still much more likely to have dropped out in 2006 (about 30 percentage points more than children of college graduates).

Sample: 15-19 year-olds; reference categories are: boy, birth in Great Cairo, uneducated mother (or missing value), uneducated father (or missing value), and father professional, manager, technician or clerk.

Table 5 documents the reasons reported for never attending school and dropping out (using information collected among 10-29 year-olds by the SYPE 2009 survey). About half of never-attenders report family or own choice as a reason for not going to school. A higher proportion for girls reported that cultural views toward gender roles still enter in these decisions. Financial constraints and opportunity costs of schooling (i.e. the foregone economic contribution of children attending school) were mentioned by 52 and 46 percent of never-attending boys and girls, respectively. Customs, traditions and marriage are cited as reasons by 24 percent of girls. Hence,

when availability of schools is not a prominent reason, lack of financial resources and cultural attitudes toward girls' schooling are the main reasons reported for never attendance. Similarly, financial constraints and opportunity costs are cited for dropping out by 60 and 39 percent of boys and girls, respectively. Avoiding mixing with the opposite gender or marriage was cited by 11 percent of girls for dropping out.

Table 5: Reasons for never attending and dropping out of school

3. Inequities in Learning Achievements

In Section 2, we showed that while there has been democratization in access to basic education in Egypt, there remain persistent disparities in access to general secondary and college education. Given that educational trajectories depend to a large extent on tracking into general and vocational secondary schools at completion of basic education, the quality of the education at lower levels of schooling is likely to be a major determinant of educational inequalities in Egypt.⁴ We now turn to inequalities in learning achievements, as measured by TIMSS evaluation of pupils'

⁴ The tracking is determined by scores at the preparatory completion exam organized at the level of governorate.

achievements, at the end of basic education (8th grade). For investigating learning achievements at completion of basic education, we use information from the TIMSS conducted in Egypt in 2003 and 2007. These surveys collected responses, from a representative sample of Egyptian eighth-8th graders, to series of items of a test-based evaluation of achievements in Math and Science. 7,095 pupils from 217 schools in 2003 and 6,582 pupils from 233 schools in 2007 were interviewed.⁵

The TIMSS surveys collected information on children's background, in particular, in addition to their gender, mother's and father's education, the language spoken at home, whether any of the parents was born abroad, household ownership of durables such as books, tv sets, satellite channels access systems, and phones. The information on the economic status of the parents is limited though, with parental, notably father's, educational attainments serving as an imperfect proxy. Besides, the surveys indicate the location of the schools, which we take as a proxy for places where children were raised.⁶ For the 2007 survey, we could use information on the governorate and area type (urban or rural) of the school location. For the 2003 survey, we could only access the area type information.⁷

Methodology for measuring learning opportunity inequality

Achievements in the TIMSS Math and Science tests are measured using item response theory models, aggregating answers from many test items of varying difficulty and discriminating power. These models treat achievement as a latent variable, and, assuming a given distribution (usually a normal) for the achievements of pupils, their estimation allows deriving its distribution and its predicted value for each individual (see [Mislevy, 1991](#); [Mislevy et al., 1992](#)). Importantly, these models recover estimates of individual achievements that come with a scale that is arbitrarily fixed.

⁵ We report the results for Math test-scores. The results for Science are very similar and available upon request.

⁶ Migrations motivated by studies should be limited among 8 graders. The SYPE survey provides no information on birth place of children less than 15.

⁷ The definition of urban areas is not perfectly consistent across the 2003 and 2007 surveys. The 2003 information relies on a classification of "communities" by population size (communities with more than 50,000 inhabitants are classified as urban), while the 2007 information is the official classification consists in the administrative classification (which was not available in 2003).

Essentially, there is no scale for measuring a pupil's scholastic ability, so that some reference levels have to be fixed for the mean and standard deviation of achievement measured by a test. International achievement tests thus fix these reference levels of mean and standard deviation for a given set of country and year, and the subsequent evaluations conducted with the same test are reported using the same arbitrary scale. In the TIMSS procedure, test -scores were normalized by fixing the mean and standard deviation of achievements of pupils who participated to the first 1995 international TIMSS survey at, respectively, 500 and 100. This standardization must be dealt with in inequality measurement.

The inequality measures to be used for documenting the distributions of test scores must account for several methodological issues. In particular they must be robust to the standardization of these TIMSS variables. However, as noted by Ferreira and Gignoux (2011a), no inequality index satisfying a set of basic desirable properties (symmetry, continuity and the transfer principle) can be both scale- and translation invariant, and thus robust to the standardization. A number of well-known inequality indices, such as the Gini and Generalized Entropy indexes, are not even ordinally equivalent, so that the arbitrary standardization could affect the ranking of different population by inequality levels.

For handling this standardization issue, we follow Ferreira and Gignoux (2011a), and base our inequality analysis on the variance (and standard deviation). Consider a post-standardized distribution of test-scores (y_{ij}), obtained as a linear function of the pre-standardization distribution (x_{ij}):

$$y_{ij} = \hat{\mu} + \frac{\hat{\sigma}}{\sigma} (x_{ij} - \mu) \quad (1)$$

The variance (or standard deviation) of a post-standardized distribution (V_j^y), for example, is a monotonic (proportional) function of the pre-standardization variance (V_j^x), and does not depend on any other moment of the pre-standardization distribution; for the variance:

$$V_j^y = \left(\frac{\hat{\sigma}}{\sigma}\right)^2 V_j^x \quad (2)$$

While it is not scale invariant, the mean (as the standard deviation) is thus ordinally-invariant to the standardization. In addition it satisfies the basic properties above (and is also additively decomposable). It thus provides a basic standardization ordinally consistent measure of inequality of educational achievement. In practice, we report the standard deviation.

In this paper, rather than overall inequality, we are mainly interested in inequality of achievement opportunity. Following [Roemer \(1998\)](#), empirical analyses of the distribution of opportunities begin by seeking agreement on a set of characteristics which are beyond the individual's control, and for which he or she cannot be held responsible. These variables are called 'circumstances'. Once a vector C of circumstances has been agreed upon, the population can be partitioned into groups with identical circumstances.

Given such partition, in one approach to the measurement of inequality of opportunity, called ex-ante and associated with [van de Gaer \(1993\)](#), the opportunity set faced by each type is evaluated using the conditional distributions of outcomes given circumstances, and equality of opportunity is attained when there is perfect equality in these values across all types. This rests on the notion that purely individual effort or ability should be orthogonal to an individual's circumstances at birth (for more discussion, see e.g. [Roemer, 1998](#); [Fleurbaey, 2008](#)).⁸ The full conditional distributions of outcomes given types or some of its higher moments can be used, but, in practice, researchers have often used the mean income (or achievement) of the type as an estimate of the value of the opportunity set they face. Since equality of opportunity would imply equality in means across types, inequality of opportunity is then naturally seen as some measure of between-type inequality. As in [Ferreira and Gignoux \(2011a, b\)](#), we thus measure inequality of opportunity (IOp) by between-type inequality, or specifically:

⁸In an alternative but closely related approach, called ex-post and associated with [Roemer \(1998\)](#), equality of opportunity obtains only when individuals exerting the same degree of effort, regardless of their circumstances, receive the same reward. See Fleurbaey and Peragine (forthcoming) for a formal discussion of the relationship between the two approaches.

$$\theta_{IOP} = \frac{I(\{\mu_i^k\})}{I(y)} \quad (3)$$

where $\{\mu_i^k\}$ is the smoothed distribution corresponding to the distribution y and the partition P .

Following [Bourguignon et al. \(2007\)](#) and [Ferreira and Gignoux \(2011b\)](#), one can obtain a parametric estimate for θ_{IOP} , based on an OLS regression of y on C :

$$\hat{\theta}_{IOP} = \frac{I(C_t' \hat{\beta})}{I(y)} \quad (4)$$

$\hat{\beta}$ in (4) is the OLS estimate of the regression coefficients in a simple regression of y on C :

$$y_t = C_t' \beta + \eta_t \quad (5)$$

In (4), the denominator is a function of the vector of predicted incomes from regression (5). Under the maintained assumption of a linear relationship between achievement and circumstances, this vector is equivalent to the smoothed distribution, since all individuals with identical circumstances are assigned their conditional mean incomes.

Following the arguments above, we use the simple variance as our inequality index $I()$. This choice yields our proposed measure of inequality of educational opportunity, as a special case of (4):

$$\hat{\theta}_{IOP} = \frac{Var(C_t' \hat{\beta})}{Var(y_t)} \quad (6)$$

This is the R-square of an OLS regression of the child's test score on a vector C of individual circumstances. Despite its simplicity, it is a meaningful summary statistic. It is a parametric approximation to the lower bound on the share of overall inequality in educational achievement that is causally explained by the joint effect of all circumstances. A formal proof is provided by [Ferreira and Gignoux \(2011b\)](#). But the basic intuition is that some circumstances remain unobserved and observing and controlling for these unobservables could only increase the share of explained inequalities. However, the estimates should not be interpreted as capturing the effects of the specific

set of circumstances considered in the analysis as they may reflect the effects of omitted and correlated individual and environmental characteristics. Individual elements of the $\hat{\beta}$ vector thus suffer from these omitted variable biases, and cannot be interpreted as causal estimates of the individual impact of a particular circumstance on test scores.

Another attractive feature of $\hat{\theta}_{IOP}$ as a measure of inequality of educational opportunity is that, unlike any measure of the level of inequality, it is a parametric estimator of a ratio (equation (3)) that is cardinally invariant in the standardization of test scores. To see this, note that any subgroup mean is affected by standardization in a manner analogous to equation (1), so that:

$$Var\{\mu_i^k(y)\} = \left(\frac{\sigma}{\sigma}\right)^2 Var\{\mu_i^k(x)\} \quad (7)$$

Given (7) and equation (2), it follows that: $\theta_{IOP} = \frac{Var(\{\mu_i^k(y)\})}{Var(y)} = \frac{Var(\{\mu_i^k(x)\})}{Var(x)}$

Finally, $\hat{\theta}_{IOP}$ is decomposable into components for each individual variable in the vector C.

Equation (6) can be rewritten as the sum over all elements (denoted by j) of the C vector:⁹

$$\hat{\theta}_{IOP} = \sum_j \hat{\theta}^j = \sum_j (var\ y)^{-1} \left[\beta_j^2 var\ C_j + \frac{1}{2} \sum_k \beta_k \beta_j cov(C_k, C_j) \right] \quad (8)$$

Beyond the specific measures to be used, an additional challenge is that the TIMSS sample is representative of eighth-graders and not of the overall population of lower-secondary school age children. An estimate of the share of preparatory-level graduates among these cohorts can be obtained from the SYPE survey: 78 percent of youth between 16 and 21 complete preparatory schooling. Thus 22 percent drop out before and their achievements are not reflected in a basic analysis of TIMSS test-scores.¹⁰ This selection is problematic for an analysis of educational

⁹This is an example of a Shapley-Shorrocks decomposition: it corresponds to the average between two alternative paths for estimating the contribution of a particular circumstance CJ to the overall variance. In the first (direct) path, all $C_j, j \neq J$ are held constant. In the second (residual) path, C_j is itself held constant, and its contribution is taken as the difference between the total variance and the ensuing variance. Either path is conceptually valid, and the Shapley-Shorrocks averaging procedure yields (8) as the path-independent additive decomposition. See Shorrocks (1999) for the original application of the Shapley value to distributional decompositions. [Ferreira and Gignoux \(2011a\)](#) provide a formal proof that (8) is the Shapley-Shorrocks decomposition of the variance into the effects of individual circumstances.

¹⁰Among those, 6.5 percent have never been to school, 4.5 dropped out before completing primary, and 11 percent

opportunities which is not concerned only in the outcomes of preparatory-level enrollees. Dropping out is extremely likely to be a selective process, in the sense that it is correlated with family and student characteristics that also affect test scores.

In this paper, we have attempted to correct for the selection biases described above. We follow Ferreira and Gignoux (2011a), and use a simple two-sample non-parametric mechanism for assessing the sensitivity of our inequality measures to alternative assumptions about the sample selection process. The procedure relies on using information on preparatory school graduates from the HIECS Egyptian budget survey from 2004-05. This large-sample survey allows estimating the numbers of preparatory-school graduates and drop-outs in groups defined by similar gender, father's education and region of residence (the two later variables have consistent coding in the two surveys). The procedure then consists in putting back observations and imputing test-scores for drop-outs in the TIMSS sample. Two extreme assumptions are used for the imputations. The first assumes selection on observables whereby drop-outs would achieve similarly to children taking the TIMSS tests that have similar characteristics. The second assumes selection on both observables and (strongly) unobservables and attributes a test-score in the lower tail (we use the 5th quintile) of the conditional distribution of scores achieved by test takers with similar characteristics. In practice, the corrections are implemented by a re-weighting of the TIMSS sample.

Learning achievement inequality: low mean and high dispersions

By applying the measures above to the TIMSS data, we first document the levels of inequality in learning achievement observed in Egypt and put them in an international perspective. **Figure 2** plots the country-level standard deviations of test scores against the mean scores in Math in the TIMSS 2007 data. Egypt, with a mean score of 391 and a standard deviation of 100, lies in the top left quadrant, i.e. has both a low mean and a high dispersion in learning achievements.

before completing preparatory.

Jordan, Oman and Palestine have similar means and inequality levels, but Egypt has one of the highest inequality levels (Turkey has an even more dispersed distribution of achievements but with a higher mean). The main implication of this pattern is that, although it also has high performers, Egypt has a large number of pupils performing very low at the TIMSS test.

Figure 2: Mean and inequality in Math test-scores: Egypt in an international comparison

Figure 3 plots the differentials in the mean test scores in Math of girls and boys by country mean. On average, Egyptian girls score 13 points more than boys in Math (397 against 384). This moderate differential in favor of girls contrasts with their lower access rates at basic education levels. A similar higher mean performance of girls is observed (and sometimes larger) in other MENA countries (Bahrain, Jordan, Palestine, Oman, Qatar, Saudi Arabia), but boys still perform better than girls in others (Algeria, Lebanon, Morocco, Syria, Tunisia). However, gender-based inequalities are not driving the large level of learning inequality observed in Figure 2.

Figure 3: Gender-differential and mean Math test-scores: Egypt in an international comparison

A high absolute level of inequality of learning opportunity

Now let us turn to inequality in learning opportunities. OLS estimates of the partial effects of circumstances on achievements in Math are reported in **Table 6**. For TIMSS 2007, we report the estimates with three different sets of geographic controls: a) urban and rural governorates; b) six regions; and c) all governorates. When more detailed geographic controls are used, the effects of gender on test-scores are not statistically significant in both 2003 and 2007. Parental education does have large effects on test-scores with gaps of about 30 between children of post-secondary graduate parents and those of uneducated parents. Other things being equal, children of parents born abroad achieve lower (by 25 to 45 points) test-scores, and there are also some differentials associated with spoken language although those speaking Arabic and another language now perform better (by 10-25 points). Ownership of a tv set, probably capturing some wealth effects, is associated with a large differential (of 20-45 points), while ownership of books with smaller (about 10 points) ones (cultural resources are probably already captured by parental education). Differentials associated with location are also large with children in rural areas performing on average 40 points lower in

2007 and those of rural Upper Egypt almost 75 points below those in urban Lower Egypt.

Source: TIMSS 2003 and 2007 surveys.

The estimates of the opportunity shares of inequalities in achievements at the TIMSS Math test are shown in **Table 7**. The results for 2007 (column 2) with a similar urban-rural specification give a lower bound for the opportunity share at 18.2 without the corrections for potential selection bias. It is lower than the corresponding figure in 2003 by 3.4 percent; the decrease has a standard error of .85 point, a statistically significant difference. It is worth noting that the 2003 and 2007 estimates are not perfectly comparable for reasons described earlier. However, the ranges obtained with the imputations for selection bias 2003 and 2007 overlap.

The two remaining columns use more detailed information on geography. The lower bound increases to 21.6 percent with the six regions school location variable (and vary between .213 and .266 with the imputations) and to 24.2 percent when accounting for the precise governorates for school locations. This increase suggests that achievement inequalities associated with geography are large. Overall, based on the most complete estimates in the last column, at least a quarter of achievement inequalities at the end of preparatory can be attributed to circumstances. This figure is comparable to those from similar analysis in other countries (e.g., the share of inequality of opportunity was found similar in countries such as UK or the US in Ferreira and Gignoux, 2012). But given the high overall learning inequalities, the absolute level of learning inequities at completion of basic education is higher in Egypt than in many other countries.

The estimates of partial shares associated with specific circumstances confirm the importance of geography. Using data on Math test-scores in 2007, 4.5 percent of inequalities are accounted for by area type in the first model, 8.3 percent by the six regions indicators in the second, and 11.2 percent by area type and governorate combined in the third model. In comparison, the next most important circumstances are parental education (3 to 4 percent for father's and about 2 percent for mother's education), and immigration status (3 to 4 percent), and ownership of cultural goods which accounts for another 3 percent. Language at home accounts for about 1.5 percent. Gender is not associated with a significant share of inequalities in achievements.

Significant achievement inequality in national exams

To investigate how learning opportunities evolve across schooling levels, here we expand the analysis to achievements at national exams at primary, preparatory, and secondary levels. For this use, we use retrospective data from the Survey of Young People of Egypt in 2009 (Asia and Office, 2011). The survey collected detailed information from a sample of 15,029 individuals aged 10 to 21. Notably, it asked information on whether individuals completed different schooling levels, and their scores in the national examinations at completion of the primary, preparatory, and

secondary levels. Examination scores take values ranging between 50 and 100. The average score is 82.0 (with standard deviation of 11.5) at the primary, 75.2 (13.2) at the preparatory, and 74.9 (12.8) at secondary levels.¹¹ We focus on scores of 12-15 year-olds at primary, 14-18 year-olds at the preparatory, and 18-21 year-olds at the secondary completion. Among these individuals, respectively, 59, 72 and 82 percent reported exam scores in the 2009 SYPE.

In addition to exam scores, the 2009 SYPE survey collected information on the background of the youth. In the analysis below, the set of variables used to capture their background include gender, governorate of birth, parental education level¹², religion (Muslim vs another religion), and family wealth, obtained from information on the durables owned by households and housing conditions, and their wealth group (i.e., consumption quintiles).

We perform the analysis of inequality in exam scores using the same approach as for learning achievements evaluated using TIMSS data above. **Table 8** reports OLS estimates of the partial effects of circumstances on exam scores. Girls tend to do better at all three exams with a gap of 2 to 4 more exam points on average, increasing with attainment, than boys. The gaps associated with parental education levels are large, ranging from 6 points for father's education at the primary completion exam to 10 points for mother's education at the preparatory. The gaps associated with family wealth are large—about 8 points at the primary and preparatory completion exams. There are no apparent differentials in scores between Muslims and non-Muslims. However, there are large differentials associated with birthplace, with scores for some birth-governorates 13-14 points higher than others at the primary and preparatory completion levels (estimates not reported, available upon request).¹³

¹¹In an alternative but closely related approach, called ex-post and associated with [Roemer \(1998\)](#), equality of opportunity obtains only when individuals exerting the same degree of effort, regardless of their circumstances, receive the same reward. See Fleurbaey and Peragine (forthcoming) for a formal discussion of the relationship between the two approaches.

¹²Note that the information on parental education is missing for children who do not live with their parents. For those children, parental attainment is coded in a missing category (we do not drop those observations).

¹³Interestingly, the gaps by birth place are lower at the secondary level, suggesting that the pupils who attain that level of education are already quite selected.

*** $p < 0.01$

The estimates of opportunity shares in the distribution of exam scores are shown in **Table 9**.

For scores at the primary completion exam, the set of circumstances used explains 24.4 percent of the overall variation in scores. This estimate varies very little with the lower alternative correction for selection, and increases to 29.1 percent with the upper-bound alternative. For scores at the preparatory completion, the uncorrected estimate is at 30.2 percent, and varies between 27.4 and 35.2 percent with the correction for selection. Finally, for scores at the secondary completion, the

uncorrected estimate is at 22.4 percent, and varies between 20.8 and 27.9 percent with the corrections.

The pattern of increasing and, later on, decreasing shares of inequality explained by circumstances may be explained by selection, which is likely to be larger at the secondary level. But the main result here is that learning opportunity inequality appears at early ages: a large amount of it (at least a quarter of achievement inequality) is already observed at the primary level. These inequities then build up to reach at least a third of learning inequality at the end of preparatory. Hence, tracking at the end of preparatory does not seem to explain all subsequent inequalities.

Table 9: Opportunity Share of Inequality in National Exam Scores

	Primary 12-15 y.o.	Preparatory 14-18 y.o.	Secondary 17-21 y.o.
Overall inequality	134.0	180.0	131.4

Sample: 12-14 y.o. primary, 14-18 y.o. preparatory, and 17-21 y.o. secondary graduates.

We also perform the decomposition of the partial shares of scores inequality associated with the different circumstance variables. Birth governorates explain again significant shares of the inequality in exam scores: about 6 percent at the preparatory, which is rather consistent with the results obtained using TIMSS data. Family background explains the largest shares of exam scores variations. Parent's educational attainments in particular explains, respectively, 12, 16 and 12 percent of the variation of scores at primary, preparatory, and secondary levels, respectively, while

family wealth explains 8, 9 and 5 percent at the corresponding levels. Gender explains a significant share of scores inequality only at the secondary exam (3 percent). Again religion has no explaining power. These results thus suggest that family resources and geography explain most of the variation in achievements at official exams.

4. Some Evidence on the Determinants of Learning Outcome Inequalities

The findings of Section 3 showed that a significant share of achievement inequality is associated with circumstances determined at birth. They also suggest that these inequities do not appear suddenly at adolescence, such as at tracking taking place at the end of basic education, but rather build progressively through primary and lower secondary schooling grades. Here we look at some of the factors affecting learning inequalities, particularly at the early years. We focus on three main factors: type of school system attended, household spending on private tutorials, and tracking. Egypt has different school systems, such as public, private (including religious) schools, some of which use English or other languages for teaching. For our analyses, we use information from the SYPE survey on the type of the primary, preparatory and secondary schools attended by teenagers, distinguishing private, public, but also experimental language and traditional schools, and on households' expenditures in private tutoring at the same levels.

Based on data from the UNESCO Institute of Statistics, **Figure 4** reports the evolution of public spending on education in Egypt, in share of GDP, and benchmarks it with the corresponding public spending in lower middle countries, Arab and Middle East and North Africa countries (note that the series of data are incomplete). It shows that public spending in education has stagnated over the long run (and decreased compared to the early 1980s) and slightly diminished in Egypt over a more recent period between 2003 and 2008, from about 5 to 3.9% of GDP. A similar evolution is observed in other MENA countries but the level of these expenditures is slightly lower in Egypt. The decline in public expenditure on education might contribute to the low learning achievement of many young Egyptians on the TIMSS test.

Different schools systems

Several school systems coexist in Egypt. The majority of schools depends on the government and teaches in Arabic, but some government experimental schools use English and other languages in addition to Arabic. Besides, many pupils attend private schools; among these, one can distinguish ordinary private schools, language schools that use English for teaching, and religiously-oriented (mainly Al-Azhar, but also Christian) schools. Schools of different systems are managed in diverse ways; for instance, private and experimental government schools, have a more decentralized administration. They also provide different levels of inputs (e.g. teachers and their qualification, infrastructures, or school materials). The attendance of a specific school also affects the network of school peers with whom a child may interact. The choice of a school system may thus have large effects on learning outcomes, and is likely to be an important channel shaping learning inequities.¹⁴

Figure 5 shows the allocation of pupils of different family backgrounds into schools of different systems, respectively, at the primary, preparatory and secondary levels. We consider a

¹⁴The levels of inputs and peers networks are also likely to differ across schools within a given system, so the analysis below is far from complete in capturing all the variations in schooling conditions.

single family background variable here: household wealth. At the primary level, the great majority of pupils - about 90 percent for each of the first four wealth quintiles - attend government schools, and about 5 percent of pupils of any wealth quintile attend Al-Azhar traditional schools. However, pupils from the highest wealth quintile stand apart, as 35 percent of them attend private or experimental primary schools. A similar pattern emerges at the preparatory level, with most pupils of the first four quintiles attending government schools, or traditional Al-Azhar, but 25 percent of pupils from the highest quintile attending private or experimental schools.

Figure 5: Attended school system by family wealth

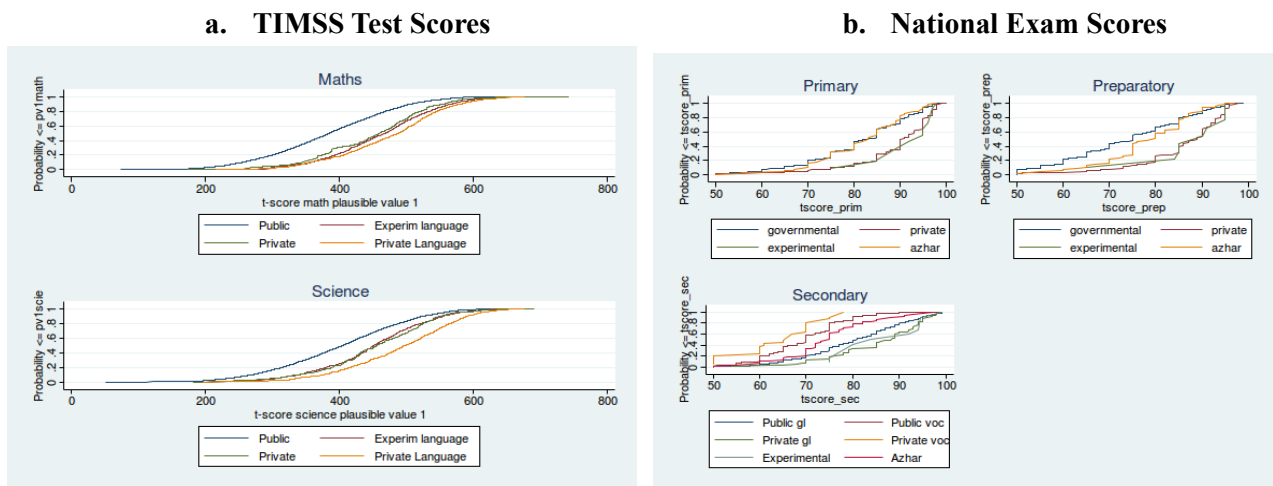

At the secondary level, after tracking into general and vocational schools, children from different family backgroundsbackground appear to be allocated into very different systems. Less than 20 percent of pupils from the bottom two quintiles attend general public or private secondary schools, and 75 percent of them attend vocational public schools. On the other hand, 75 percent of pupils from the highest quintile attend general public secondary schools. This reflects the tracking into general and vocational education at entry into senior-secondary schooling.

Figure 6 (left panel) shows, using cumulated density functions, the distributions of TIMSS test-scores for children attending preparatory schools of different systems. The distributions of test-scores of pupils in regular government schools are stochastically dominated by in other school systems. And there are very large achievement gaps across school systems: the average Math

(Science) test-scores are respectively 384 (402), 464 (451), 451 (455), and 478 (491), in public, experimental language, private and private language preparatory schools, Therefore, average scores are, respectively, .8, .7 and .9 standard deviations higher in experimental language, private and private language schools than in regular public schools.

Figure 6: Distribution of Learning Achievements by Educational Systems

source: 2009 SYPE and 2007 TIMSS data

Similarly, **Figure 6** (right panel) shows the distributions of scores at official exams, at primary, preparatory and secondary level, for children who attended schools of different systems. At the primary and preparatory levels, exam scores in regular public schools span over a wide range of achievements, with some pupils in public schools also achieving high scores. However, the distribution of scores of pupils in government (or traditional Al-Azhar) schools are again stochastically dominated by those in private and experimental schools. And, at the primary level, pupils in private and public experimental schools achieve exam-scores that are in average .7 and .8 standard deviations above the average of regular public school students. At the preparatory level, the differentials increase to reach 1.0 and 0.9 standard deviations.

At the secondary level, the gaps have widened but are now between general and vocational schools. Very few pupils in (public or private) vocational schools achieve high exam-scores. Average exam-scores are respectively 1.6, 1.2, and 0.9 standard deviations higher in private language, private general and public general secondary schools than in public vocational secondary

schools.

The pattern emerging from this description is that of large and increasing achievements gaps across schooling systems, with a divide between public regular and private or experimental schools at the primary and preparatory levels that is replaced by disparities between vocational and general schools at the secondary level.

If attending private schools allows children from advantaged backgrounds to perform better at the preparatory exam, allocation by school type, and attendance of a private school at the primary and preparatory levels, could contribute to educational inequities. However, rather than the school system, the differentials might just be explained by the selection of children with different characteristics into different school systems, such as the effects of other resources associated with a child's background. To investigate this, **Table 10** reports the estimates of the equity-shares of learning achievements after controlling for the school system attended. The intuition underlying the analysis is that the controls should cancel out the indirect effects of a child's circumstances through attendance of a different system. Thus comparing the share of achievements inequities in the uncontrolled and controlled analysis should inform on the differentials that stem from having benefited from a different system and associated schooling environment.¹⁵

¹⁵We rely here on OLS estimates of the effects of attending different school systems. An obvious limitation is that the estimates will be biased as soon as some unobservable variables that affect learning outcomes are associated with the school system attended.

Table 10: Opportunity Share of Inequality in Test and Exam Scores Controlling for the Allocation into Different School Systems

	TIMSS Math test	Primary exam	Preparatory exam	Secondary exam
Base results	0.216	0.244	0.306	0.224
School system controls	0.211	0.240	0.303	0.180
School fixed effects	0.0718			

Sample: SYPE 2009, samples of 12-14 y.o. primary, 14-18 y.o. preparatory, and 17-21 y.o. secondary graduates; source: SYPE 2009 survey.

The results suggest that, at the primary and preparatory levels, attendance of different school systems contributes very little to inequities in learning achievements. Taking the baseline uncorrected estimates as reference, and using data either from TIMSS test-scores or from the primary and preparatory completion exams in the SYPE survey, the share of achievements inequalities associated with a child's circumstances remains virtually the same when controlling for attended school system. This suggests that, had they attended the same school systems, the gaps between pupils from different backgrounds would not have differed.¹⁶

On the other hand, tracking into general and vocational secondary schools at the secondary level does explain a significant share of learning achievements inequities. Although circumstances continue to drive large learning differentials, controlling for school type does reduce significantly their effects (the estimated lower bound decreases from 22 to 18 percent). Hence, while a significant share (25 to 35 percent) of pupils from more privileged background attend private schools, we do not observe that this allocation explains a large share of achievement differentials at the primary and preparatory levels. However the tracking of children from different backgrounds into general and vocational schools does seem to contribute to achievements gaps at the secondary level.

¹⁶ Introducing schools fixed effects does reduce considerably the estimates of the share of unequal opportunities - to 0.0781 for the TIMSS test-score at completion of preparatory -, suggesting that a large part of those inequities is captured by the attendance of different schools. However, this decrease is difficult to interpret as it also includes the effects of living in different neighborhoods (and more generally geography) and related family characteristics.

Private expenditures in tutoring

We now turn to the role of private expenditures in tutoring. **Figure 7** shows average levels of these expenses, at the primary, preparatory and secondary levels, for children from different backgrounds. According to SYPE 2007, respectively 58 percent and 64 percent of pupils at the primary and preparatory levels receive paid tutoring (mostly private tutoring but some also follow after class study groups).¹⁷ Average monthly expenditures in tutoring and pupil (including zeros) are 35, 54, and 88 Egyptian Pounds, respectively, at the primary, preparatory, and secondary levels.¹⁸

Figure 7: Tutoring expenses by circumstances

There are also large variations by children's background. Families spend much more in tutoring for girls (about 117 pounds at the preparatory) than for boys (65 pounds).Pounds) at the

¹⁷ This share decreases to about 50 percent at the secondary level, which emphasizes the link between tutoring and preparation of the preparatory completion exam.

¹⁸ In late 2007, an Egyptian Pound was about .18 US dollar.

preparatory. More strikingly, families of the highest wealth quintile spend about ten times more than families in the bottom wealth quintile, and the same is true when comparing the expenditures of parents with a college education with those of uneducated parents. For instance tutoring expenditures reach 340 pounds for preparatory pupils whose mothers have a college degree. Expenditures in tutoring are also much higher for pupils born in urban governorates (210 pounds in average at the preparatory level) than in rural ones (35 pounds in rural Egypt).

Thus tutoring expenditures, which are large and strongly linked with a pupil's background, are likely to contribute to learning achievement inequities. To investigate, we re-estimated the effects of pupils' circumstance characteristics on differentials in learning achievements after controlling for families' expenditures in tutoring. We use as control the logarithm of total household expenditures in tutoring divided by the number of enrolled children.¹⁹

Table 11: Opportunity Share of Inequality in National Exam Scores Controlling for the Expenditures on Tutoring

	Primary	Preparatory
Overall inequality	128.1	177.6
Base results	0.223	0.298
Tutoring household expenditures control	0.211	0.259

Source: SYPE 2009 survey.

Sample: 12-14 y.o. primary, 14-18 y.o. preparatory, and 17-21 y.o. secondary graduates.

Table 11 reports the estimates of the equity-shares of learning achievements after controlling for the levels of household expenditures in tutoring at the primary and preparatory levels. These are obtained using the SYPE 2009 data. Taking the baseline uncorrected estimates as reference, the opportunity share of inequalities in achievements at the primary exam decreases only slightly from 22.3 to 21.1 percent when controlling for tutoring expenditures. But, even if it remains high, the corresponding share in achievements at the preparatory exam decreases much more

¹⁹Of course, there are quite serious identification issues here. In particular, although averaging at the family level should mitigate this concern, tutoring expenditures are likely to depend on a child's scholastic ability.

drastically from 29.8 to 25.9 percent. Abstracting from the possible identification concerns, this suggests that, were parents to spend the same amounts in tutoring, gaps in achievements at the preparatory completion exam between children of different background would diminish by about 13 percent. Although a more causal analysis would be required, this descriptive finding suggests that differentials in tutoring expenditures do contribute to inequities in achievements at completion of basic education.

5. Conclusions

This paper documents inequalities in educational achievements at basic and secondary education levels in Egypt and the extent to which these are associated with circumstances lying beyond the control of students, and investigates the contribution of potential institutional and behavioral factors to learning outcome inequalities.

Evidence from different sources of data suggests that, although basic education has been democratized, some inequities in access to general secondary and college education have persisted over the past two decades. The number of pupils tracked into vocational secondary schools has increased faster than those tracked to general secondary schools, and family background has become a more and more decisive factor in tracking.

Relying on recent methodological developments for the measurement of inequality of opportunity, the report estimates lower bounds for the opportunity shares of inequality in educational achievements. At least a quarter of inequalities in preparatory pupils' TIMSS test scores can be attributed to pre-determined circumstances. With regard to national exam scores, the opportunity share of achievement inequalities is estimated to represent at least a third of overall inequalities at completion of preparatory schools and is already high, explaining at least a quarter of inequalities, at completion of primary. While these shares are intermediate in an international perspective, the high level of overall achievement inequality observed makes inequities in learning opportunities between Egyptian youth high compared to other countries in absolute levels.

Moreover learning gaps among pupils from different backgrounds appear at early grades and are largely associated with geographic and family backgrounds.

These early inequalities in learning opportunities seem to result from both heterogeneous family cultural and financial resources and the institutions of the Egyptian educational system, with tracking reinforcing unequal family resources and early learning gaps. While finding no conclusive evidence that attendance of different school systems (public and private and experimental schools) at the primary and preparatory levels has significant effects, the results suggest that the high and unequal levels of household expenditures in private tutoring significantly contribute to achievement inequalities. Policy reforms to address inequity concerns therefore might need to deal not only with tracking and mobility in the educational system at upper levels, but also with learning gaps among younger pupils.

More causal analysis of the channels driving inequality in opportunities for learning achievements in Egypt is of course needed, as the empirical evidence remains scant. Future studies could focus on the effects of tracking of pupils at completion of preparatory school, deepen the analysis of school inputs (including within school systems) such as school management, and the effects of expenditures in tutoring and other private investments in education.
