The study was directed by Dr. Zeba A. Sathar, and Dr. Arshad Mahmood led the analysis of FALAH data to set the background and to identify the areas that needed in-depth qualitative exploration. Several other team members, namely Aiasha Shafique, Asifa Irum, Atif Farooq, Muhammad Asim, Syed Taimur Ali Shah, and Tayyab Aziz assisted in the qualitative data collection, analysis, and report writing to whom we extend our appreciation. We would also like to acknowledge the contribution of Kanwal Eshai and Anushe Hassan in editing and Ali Ammad for the layout of the report.

We are extremely grateful to the World Bank for initiating and supporting this study and Drs. Kostermans, Haq, and Kashif for their valuable comments.

Most of all, we would like to thank the respondents of the study who gave their time and voluntarily participated in the focus group discussions and in-depth interviews. Without their honest and patient responses we would not have been able to generate such useful data and insights from Punjab.

Executive Summary

This study has a twofold aim of exploring couples' dynamics during their decision processes regarding fertility intentions and practices along with community perceptions of male-focused interventions and men's suggestions for future intervention strategies.

The findings are based on three data sources. The primary data source is a 2013 qualitative study in four districts of Punjab province. The second data source is secondary analysis of the baseline and endline surveys of the Family Advancement for Life and Health (FALAH 2007-2012) project1. The third data source is the Pakistan Demographic Health Survey (PDHS) 1990-19912 and 2006-2007, which were used to assess trends over two decades.

The 2013 qualitative study was in four districts of Punjab, namely Jhelum, Bahawalpur, D.G. Khan, and Okara. The first three were FALAH districts in which interventions were tested, while the fourth was chosen as a control district. A total of 12 focus group discussions were conducted with men, and in-depth interviews were conducted with 26 couples in these districts. Data from 2,649 men and 638 couples from the FALAH baseline and endline surveys were analyzed to assess the impact of FALAH male-directed interventions on fertility intentions and behavior.

Changes in men's attitudes towards family planning: The study points to a real change in men's attitudes towards family planning in the Punjab and their readiness to be involved in family planning programs, through increased access to information and services. Punjabi men appeared to be more concerned about their fertility intentions and behavior than they were in the 1990s. Since men are considered the primary earners and decision-makers in households in Pakistan, their primary motivating force is the growing economic challenge leading to an inability to meet household costs. Both qualitative and quantitative data confirm this change.

Increasing spousal communication aids decisions on fertility issues: Economic concerns also provide leverage in improving communication between husbands and wives on family size and contraceptive use. This pattern suggests it is no longer wives' exclusive responsibility to initiate discussions about their fertility intentions. Although there may be a divergence in opinion on ideal family size and contraceptive use or choice of method, increasing spousal communication makes it easier for women to convince their husbands about the need for family planning. A series of follow up discussions may be necessary, however, for women to convince their husbands before reaching full agreement.

Supply side issues impede men from using contraceptives: The study emphasizes that supply side issues, including lack of availability of family planning services and contraceptive methods, method failure, and contraceptive costs impede men from using contraceptives, despite men's increasing acceptance of family planning and spousal communication. In addition, limited knowledge of specific family planning methods, perceived or experienced side effects of modern methods, and lack of provider skills for managing side effects, also act as barriers to family planning method use.

Definite receptiveness towards male group meetings: The study shows strong interest among men for involvement in male-focused interventions in family planning programs. It is evident from the FALAH endline survey that male group meetings are an intervention with the most significant role in changing

---

1 FALAH project was led by Population Council with USAID funding. It was an initiative to increase adoption of birth spacing (BS) behavior and practices, with a new focus on men.

2 This was the only PDHS where men were also interviewed.
fertility intentions and practices of couples compared to other FALAH interventions. Male group meetings are suggested (both by men and women) as the most appropriate intervention for providing men with method-specific knowledge and the importance of family planning use. Men see male group meetings as having potentially more impact than women’s meetings, since educating and convincing the primary decision-makers (husbands) results in concrete steps to be taken by men themselves for practicing family planning. A suggested male group meeting strategy includes involving local persons to organize meetings and an educated and skillful outsider (preferably a doctor) to conduct them. The strategy also includes immediate provision of contraceptives after the meeting so men who want to start using contraception are not delayed.

**Women favor involving religious leaders as an intervention more than men:** Similar to FALAH endline results, the qualitative study shows mixed opinions on involving religious leaders in family planning programs, with women more in favor of involving religious leaders than men. Those in favor of involving religious leaders further suggest that religious leaders should be trained and should discuss family planning with reference to the Quran and Hadith. Generally, this suggests that religious leaders can and should play a supportive role by communicating and endorsing the message that family planning is permitted in Islam.

**The role of the media is limited:** Men were generally not very appreciative of the role of broadcast media in communicating family planning messages, mainly due to the impression that neither television nor radio can fulfill men’s need for details on contraceptive methods, which are not deemed appropriate for television or radio. Women showed greater interest in interventions through broadcast media and proposed telecasting drama series on the topic in local regional languages.

**Demand for male health workers:** Appreciating the role and effectiveness of the government’s Lady Health Worker program, men suggested recruiting male health workers in communities, with roles similar to Lady Health Workers, providing services to men at the community level.

**Conclusion**

Men are now more concerned about their fertility intentions and practices due to the financial challenges of raising large families. This concern has not only increased spousal communication about family size and contraceptive use but has also encouraged men to practice family planning. Most men now realize that either they or their wives should use family planning. It is the next step, however, of translating intention into practice, which is a challenge. Supply side issues, including the absence of, or limited, family planning services, perceived or experienced side effects of contraceptive methods, and poor quality of services, including service providers’ lack of capability to manage side effects, are the main factors hindering couples’ adoption of family planning.

Men’s positive attitudes and their readiness to be involved in family planning programs suggests that the phase of convincing men to use contraceptives has been effective and this is an ideal time for direct interventions for men in Punjab.

Spending extensive resources on media campaigns may not be as effective as interpersonal interventions. A focused effort to mobilize men through male-specific interventions is likely to increase the demand for contraceptives. However, these interventions have to be backed up by an improvement in the supply of contraceptives and availability of family planning services in accessible facilities.
Recommendations

- In Punjab, men need to become the primary focus of family planning programs. Male-specific interventions are urgently needed, and need to be introduced, to augment men’s lack of knowledge of family planning methods, encourage timely decisions on fertility issues, and increase contraceptive use.

- Men express the need for frequent male group meetings with full geographic coverage, facilitated by a local or community resident. They should be conducted by an ‘outsider’ health professional (preferably a doctor), however. Thirdly, to minimize delay in contraceptive uptake, contraceptives should be made available at the end of these meetings.

- Interventions involving religious leaders should play a supporting role in increasing acceptability of family planning among men. Religious leaders should be trained to deliver messages communicating that birth spacing and family planning are allowed in Islam.

- Supply-side barriers to family planning use exist, and regular supplies to clients should be ensured.

- Service providers should be knowledgeable and skillful, and they should also be provided with training on managing side effects to increase and sustain family planning use.
Introduction to the Study

Background

Pakistan’s slackening in its fertility transition is a cause of concern internationally, as well as within the country. High levels of unmet need for family planning, coupled with a low contraceptive prevalence rate, are believed to be closely linked with both demand and supply factors. Concerns related to supply side issues range from the unavailability and inaccessibility of family planning (FP) information and services to the quality of the services themselves, including provider-client interactions (Sathar and Zaidi 2011). Decision-making within households—particularly the low levels of female autonomy that restrict women from making decisions, and poor communication between spouses, who may not necessarily agree on fertility intentions—is considered an important constraint in seeking FP services (Bongaarts et al 2012).

Pakistan is a setting where women are generally subordinate to men. Studies repeatedly identify the husband’s agreement as one of the most influential contributors to acceptance of a FP method in both rural and urban areas (Mahmood and Ringheim 1996; Tuloro et al. 2006). In male-dominated societies such as Pakistan, the decision-making power of the husband or his mother may be critical for FP outcomes (Agha 2010). Whether actual or perceived, men’s views and decision-making powers do play an important role in seeking reproductive healthcare ranging from delivery, antenatal care, immunizations, and especially FP (Bongaarts et al. 2012; Khan et al. 2002; Agha 2010).

Assessing men’s views has been difficult due to the dearth of data and infrequent use of men as informants in health surveys and consultations. The Demographic Health Surveys (DHS) have provided the worldwide public health community with a comprehensive set of data on knowledge, attitudes, and practices for reproductive health. For the most part, only women of reproductive age are interviewed for these surveys, except for the 1990-1991 DHS that had a special module for men (National Institute of Population Studies (NIPS) and Macro International Inc. 1992). Men were not interviewed in the Pakistan DHS (PDHS) 2006–2007, however.

There are a few notable studies on the topic of men and couple decision-making in Pakistan, largely based on PDHS 1990–1991 (Mahmood and Ringheim 1997, Kiani 2003) and male data from two studies in Punjab in the 1990s (Casterline et al. 2001, Ali 1999). All of these studies emphasize the significance of involving men in FP programs and enhancing spousal communication to increase contraceptive uptake. Furthermore, studies on couples’ behaviors are especially illuminating, as discrepancies between husbands and wives may often be reasons for either inaction or inability to use contraception effectively over time to avoid unwanted pregnancies (Kazi and Satham 1997, Population Council 1997, Mason and Smith 2000).
Considering the fact that “men’s participation and sharing of responsibility in the practice of FP” was a recommendation of the 1994 International Conference on Population and Development, the lack of practical and programmatic implementation of this recommendation within Pakistan is a problem that needs to be addressed (Lasee and Becker 1997). A study in southern Ethiopia creates a comprehensible global backdrop to our research interest by pointing out that “Family planning programs should not only focus on women, but they should also address men…Until recently, family planning programs have mainly focused on women’s attitudes and behaviors” (Tuloro et al. 2006, p. 152).

The reason that researchers argue for this behavioral paradigm is the perception of women as child bearers, and consequently, the primary recipients of information and education on contraceptive knowledge and use. The attention given to them is not only considered their prerogative, but is also seen as more relevant than men’s contraceptive practices. As a result, men’s roles (who strongly influence the family’s decision-making processes in patriarchal societies) end up ignored (Tuloro et al. 2006). Therein lies the weakness in most FP programs: an essential center of agency in the dialectical process of decision-making is ignored by giving little or no attention to the understanding of men’s roles in the “effective utilization of contraceptives.” The authors conclude, “Men also play a considerable role in the decision-making process, which is a good argument for involving them in family planning activities… Family planning programs should not focus only on women, but also address men as principal stakeholders” (Tuloro et al. 2006, p. 158).

Studies in other regions have shown that one reason women give for nonuse (of FP methods) is the husband’s disapproval. This sentiment is even echoed in many developed societies where it has been shown that the husband’s desires have an important effect on a couple’s fertility (Lasee and Becker 1997). A joint study published in 2005 sought to determine the number of children considered to be “ideal” by Pakistani husbands and the factors that were associated with it (Avan and Akhund 2006). It was an attempt to specifically study male perspectives within the given research domain. Furthermore, it urged programs that focus on FP to reevaluate their primary unit of analysis: “Family planning programs should focus upon families as a whole unit of intervention rather than just focusing on wives” (Avan and Akhund 2006). The authors cited an excessive focus on women as one of the reasons for Pakistan’s slow progress in terms of FP and a declining population growth rate. Their study was cross-sectional and hence the respondents’ husbands could not be followed up to see whether their perceptions regarding the ideal number of children had translated into reproductive behavior. Moreover, while the study focused on rural villages within Khairpur district in Sindh, the authors indicated a need for a separate study that could present an urban perspective as well (Avan and Akhund 2006). Similarly, Agha (2010) highlighted the need to have complementary ‘target audiences,’ such as mothers-in-law and husbands in FP behavior change campaigns. He further emphasizes that programmatic investments in the future will prove to be futile in the absence of ventures that seek to assess the “successes and failures of specific interventions” (Agha 2010).

In the context of male involvement, a qualitative study conducted by Population Council, Islamabad in 1997 gauged the perceptions, concerns, and needs of men regarding male involvement in reproductive health in five districts of the Punjab province. The study highlighted the fact that men were not opposed to FP. However, their resistance seemed to exist mainly due to ignorance (Ali 1999). The study also suggested a split between men’s awareness and knowledge regarding FP. According to the study, men had some awareness of FP topics but did not actually know about the variety of methods available or their use. Therefore, the need to provide information on side effects and modes of action, and correct male misconceptions was strongly felt (Ali 1999).
In the study *Knowledge, approval, and communication about family planning as correlates of desired fertility among spouses in Pakistan*, Mahmood and Ringheim (1997) used data from PDHS 1990–1991 to identify factors associated with desired fertility in Pakistan. Their findings lead them to conclude that well-planned efforts to educate men about reproductive and child health and to expedite inter-spousal communication would help couples achieve their reproductive goals. Whereas the attainment of a sustainable level of fertility presupposes an improvement in the status of women, be it through education or otherwise, male involvement cannot be ignored. With regard to PDHS, the authors asserted, “Our analysis suggests that a lack of attention to men’s role in fertility is a shortcoming of the program.” They highlighted and reiterated the vantage point that needs to be adopted by local organizations working in the domain of FP: “in the cultural context of Pakistan…all efforts in promoting family planning require involving men” (Mahmood and Ringheim 1997).

The same authors in another study identified the extent of inter-spousal communication as an important factor that has an impact on fertility regulation within the Pakistani socio-economic milieu. They asserted that communication between a husband and wife “has been found to be associated with favoring a fewer number of children and with enhancing the practice of contraception” (Mahmood and Ringheim 1996). The authors also discussed changes within the ‘family norm’ that may be induced by an open discussion of personal aspirations for children by couples. The importance of focusing on male agency was stated once again, echoing their general worldview: “…many forms of contraception require partners’ participation or concurrence…Past research also shows that the role of husbands in household and reproductive decision-making is significant” (Mahmood and Ringheim 1996). After it has been established that an increased level of husband and wife communication about FP among a range of topics with gender dimensions can be conducive to the advancement of contraceptive use within couples, the authors highlighted certain areas that need to be examined in future demographic studies. One of these was the ‘empirical examination’ of the question as to whether communication between husbands and wives promotes mutual agreement in family size desires or not. In the same vein, the authors concluded by pointing out a gap within academic literature (pertaining to FP) that needs to be addressed: “While it is true that interpersonal and community-based communication approaches have not been widely tested in the field of FP in Pakistan, small-scale studies have shown the potential for success and invite further exploration” (Mahmood and Ringheim 1996). Furthermore, a focus on inter-spousal communication needs to be conjoined with an effort to influence the husband’s awareness and attitude towards FP (Mahmood and Ringheim 1996).

In a qualitative study, exploring the choices of contraception and abortion among couples living in a rural Punjabi village of Pakistan, authors found a virtual absence or very infrequent communication between husbands and wives regarding their fertility intentions particularly early in their reproductive lives (Kamran et al. 2011). The authors emphasized that the lack of spousal communication results in the inability to understand fertility intentions and desires of spouses. This late initiation of discussion results in later uptake of contraception resulting in a number of unwanted pregnancies because of the delay in getting husbands’ approval. Spousal communication appeared to have a close relationship in decision making regarding contraceptive use or seeking abortions to avoid unwanted fertility. The authors conclude by recommending the need to promote spousal communication about family planning to encourage couples to discuss fertility intentions in their early reproductive lives, which can lead to mutually informed decisions regarding contraceptive use (Kamran et al. 2011).
In their study *Husband-wife communication about family planning and contraceptive use in Kenya*, Lasee and Becker (1997) problematized the notion of inter-spousal ‘communication’ by introducing three sub-variables that touch upon different dimensions of effective communication-agreement in approval, discussion between partners, and spousal perception of the partner’s approval of FP. They stated that previous studies have defined ‘communication’ in different ways while very few have used all three dimensions properly. They also assumed that communication between spouses about FP discourages couples from having unwanted children and encourages contraceptive use. The results of their study showed that both approval of FP and knowledge of sources of contraception had the expected significant associations with contraceptive use in bivariate analyses. However, when the variables were analyzed in conjunction with the communication variables in a multiple logistic regression, it was found that the wife’s perception of her spouse’s approval of FP was statistically significant, and emerged as the most powerful variable in explaining contraceptive use. The authors stated that global studies on spousal perception are limited, and mentioned the need by all FP communication efforts to target men (Lasee and Becker 1997).

**Objectives**

Most of the research on couple dynamics and reproductive intentions and behavior for Pakistan dates from the 1990s. There is a need for a clearer grasp of current realities of couple level decision-making dynamics regarding the adoption of family planning and birth spacing behavior for the past decade. In particular, the views of men are required to assess whether men are a hindrance for women wanting to use family planning services and whether their assumed adversarial role is still real. Fresh evidence is required about discrepancy between intentions and the future desire for children, and views about contraception between men and women and husbands and wives. Secondly, since Pakistan sorely needs to reduce unmet need by improving contraceptive prevalence rates, there is a need to assess whether men themselves are in need of certain interventions to improve their approval and uptake of family planning. The objectives of this study were to explore and analyze:

a) Differences between men and women regarding fertility intentions and practices;

b) Decision-making processes among couples regarding fertility intentions and practices;

c) Local community perceptions about male-focused interventions;

d) Local community suggestions and critiques for intervention strategies in the future.

This study seeks to explore the decision-making process of couples in the move from intentions to fertility behavior. It also examines the readiness of men to be involved in FP programs through different male-centered interventions. In-depth interviews (IDIs) with couples are especially direct in gauguing spousal perception of the partner’s FP approval or disapproval. Our study focuses on urban and semi-urban areas of Punjab province and can be used, at least indicatively, for interregional and temporal analyses within the Pakistani context.

The Population Council-led and USAID-funded project, Family Advancement for Life and Health (FALAH 2007-2012) was a national initiative aimed to bring about an increase in the adoption of Birth Spacing (BS) behavior and practices—with a new focus on men among other socially influential people. FALAH focused on communications interventions which included Male Group Meetings (MGMs), religious leaders’ (RLs) involvement, and the media. Baseline and endline surveys were carried out to assess the effect of the interventions.
FALAH implemented interventions in the districts of Bahawalpur, Rajanpur, and D.G. Khan from southern Punjab and Jhelum from northern Punjab. Three of these districts (Bahawalpur, D.G. Khan, and Jhelum) were chosen for this study and a fourth, non-FALAH district, Okara from central Punjab, was randomly chosen as a comparison. Two rural communities and one urban community were chosen from every district.

Although coverage of the FALAH interventions (described later) was limited to a certain number of communities, positive results of male interventions have provided us with the basis to conduct this qualitative study. These include insights and evidence comparing the impact of interventions addressed to women (which enable them to communicate better with husbands), interventions directed through the mass media at both men and women, and above all, interventions addressed at men alone. Further analysis from the FALAH baseline and endline data is also included in this report.

While the current study was shaped by findings from men and couples in the FALAH endline and baseline surveys, it was driven by the compelling need for deeper information about inter-spousal communication and decision-making. Taking these factors into consideration, several meetings of the core team were held in order to discuss and identify the themes to be included in the guidelines. The guidelines were then field-tested (two FGDs and two IDIs) at a site in Rawalpindi. The guidelines and field strategy was further refined in light of the feedback gained. The following two themes were identified:

**Theme 1: Inter-spousal communication:** Regarding the ideal family size, the decision-making process regarding family size, and the decision-making process regarding contraceptive use.

**Theme 2: The role of interventions:** Whether respondents report knowing about any prior interventions in the FALAH districts, perceptions about MGMs, involvement of RLs/Ulema, media campaigns, and the role of Lady Health Workers (LHWs) and male mobilizers.

Separate guidelines were developed for IDIs and FGDs with phrasing modification depending on the context. The categories of men/women had to be separated in the case of couple IDIs, as they had to be gender-specific. The aforementioned themes were covered in all of these guidelines (Appendix D and E).

**Methodology**

**Study Tools**

The following data collection tools were utilized to glean information and insights mainly from men (but also a few women) using largely qualitative techniques given the sensitivity deemed to surround family planning issues:

- **Focus Group Discussions:** A total of 12 FGDs were conducted with men across the four selected districts in Punjab. Of these, eight were conducted in rural settings, while the remaining four were conducted in urban or ‘semi-urban’ areas. The men were selected on the basis of their marital status (married) and age (below 45 years). The discussions were centered on the need to assess the nature and strength of their fertility intentions, whether or not they wanted to seek more information about contraception and FP, whether they were influenced by religious or community endorsement to uphold certain values, and whether the mass media influenced their personal beliefs and values. Their views about potential interventions directed at men were also noted.
The moderators were given guidelines to follow during the FGDs and IDIs. Although this gives the semblance of these instruments being formally structured, they were implemented merely for interpretative purposes. The moderators exerted their judgment to mold the discussion according to the context. FGDs were given precedence as they helped to synthesize local community-based suggestions and critiques for intervention strategies in the future. IDIs were conducted as complementary exercises and helped our understanding of inter-spousal decision-making processes regarding the desired or planned number of children, contraceptive use, and FP at an experiential level.

b) **In Depth Interviews:** Although 20 IDIs with couples were initially planned, the research team ended up conducting IDIs with 26 couples across the four districts. The criteria for selection were as follows: the respondents had to be married, under 45 years of age, and have had at least one child. Interviews with spouses were conducted simultaneously in different rooms in order to prevent interactions that could skew the course of information being provided.

c) **Key Informants:** The respondents for IDIs and FGDs were identified by our key-informants in their respective communities. These informants belonged to district Health and Population departments and NGOs working at the grassroots level. Their involvement helped eliminate or diminish any trust barriers that might have existed within respondents, given the sensitive nature of the topics under consideration.

d) **Profiling:** Community profiles were created through semi-structured questionnaires to gauge essential development indicators of the communities. This profile assessed markers such as population, number of households, health facilities, the general economic situation, and women’s economic activities (Appendix A).

e) **Household survey data collected for the FALAH evaluation:** Household surveys were conducted to evaluate the FALAH project in the 14 selected districts of the project (Mahmood 2012). We utilize data from these surveys and particularly responses from men (2,649) and couple (638) level data to assess the impact of male-directed interventions on fertility intentions and behavior.

### Respondent Recruitment

IDI respondents had to meet the minimum selection criteria of being married, aged under 45, and have had at least one child. The need for at least one child was essential as the study examined inter-spousal communication regarding the desired/actual number of children and contraception usage status. Gauging these factors is relatively challenging with couples who are childless or just married. Despite the ‘under-45’ criterion, the sample still included some slightly older respondents. Some younger couples participated as well, which helped enrich the analysis.

FGD participants were identified and assembled by local key-informants in their respective communities. In fact, it would not have been possible to conduct FGDs without these individuals. The discussions themselves were conducted at neutral locations in the community where everyone would be able to assemble without facing external disturbances. On average, 10 respondents participated in every discussion. The minimum criterion of ‘at least one child’ was eliminated for the FGDs as a generalized community-based response was being sought.
**Ethical Considerations**

Ethical considerations were taken into account while conducting field research to ensure that respondents would not be at risk at any stage. The protocol was approval by the Population Council’s Internal Review Board (IRB) in New York. All respondent participation at all stages was purely voluntary and based on informed consent (Appendix B and C).

All participants were briefed on the identity of moderators and transcribers, Population Council’s background, the purpose and benefits of the study, and the interview process. They were told that their names would not be used anywhere and that the organization was merely interested in recording their ideas and suggestions to incorporate them in a potential intervention strategy in the future.

Apart from confidentiality, interviews were conducted after gaining permission from respondents at a time and place that was convenient for them. Moreover, keeping in view the local mores and patterns of interaction between members of the opposite sex, moderators and participants always belonged to the same gender.

**Data Recording and Processing for Analysis**

Raw audio data were recorded with participant consent using digital recorders that allowed playback for transcription purposes. All transcribers had social science backgrounds and were present throughout the interactions. They supplemented the audio data with written notes.

Recorded files were transferred to computers daily and managed in a systematic manner by assigning a unique identification number to each field interview. The research team transcribed the recordings from Punjabi/Urdu to English immediately after returning from the field. This was done in order to ensure that data was preserved and documented while still fresh in the researchers’ minds. A thematic matrix was constructed in MS Excel® after the transcriptions were complete, and was filled in by members of the qualitative research team for analysis.

**Study Limitations**

Only two or three couples could be interviewed per community due to the time schedule. Increasing the numbers of couple interviews would have enhanced the reliability of the field of responses. Secondly, another challenge faced by the moderators was participants’ hesitation to talk about certain facets of fertility behavior. Although a majority of the respondents exhibited no hesitation in discussing the number of children they had or possible intervention strategies, a degree of resistance was felt whenever the couple level decision-making processes was discussed, or whenever they probed whether wife or husband initiated the discussion. Thirdly, there was some general information, especially pertaining to the number of children and their exact ages, which proved challenging in terms of recall. This problem was more pronounced among male respondents during IDIs.
Fertility Intentions, Communication, and Decision Making About Family Planning

This chapter focuses on the fertility intentions and the decision-making process leading to contraceptive use with a special emphasis on inter-spousal communication. It includes analysis from FALAH endline data on desire for additional children, FP approval, and contraceptive use of couples, men, and women. The main findings, however, were drawn from the qualitative study. While FALAH data were used to establish overall reproductive patterns, the qualitative analysis explains the consistencies and differences observed in the quantitative analysis among men and women, in reporting their fertility intentions and behavior. The qualitative data was collected using IDIs of women and their husbands individually, and through FGDs of husbands, separately.

Table 1 compares fertility intentions and behaviors from three data sets: the 2012 FALAH endline survey, PDHS 1990–1991 (the only available data source on men), and PDHS 2006-2007 for women in Punjab. The overall comparison suggests substantial change in men’s and women’s fertility intentions and behavior for this period of more than 20 years. The findings of the FALAH endline suggest that the majority of men and women of Punjab desired no more children; this figure rose from 34 percent to 61 percent for men, and from 41 to 53 percent for women, reflecting a much more prominent change in men’s desires. In 2012 men in FALAH districts of Punjab actually had a stronger preference than women to avoid additional children, while women’s desires for controlling fertility were stronger in 1990-91. Surprisingly, PDHS 1990-91 data shows higher FP approval among men compared to women. Conversely, according to the FALAH endline survey, although men were slightly less likely to approve of FP than women, more than 82 percent did approve when the question was framed as birth spacing rather than limiting. It was also observed that men, in the smaller sample interviewed, were more likely to report contraceptive use (43%) compared to women (37%), echoing the 1990-91 pattern. A systematic increase in contraceptive use is observed among women of Punjab, from 13 percent in PDHS 1990-91, 33.2 percent in PDHS 2006-07, and 36.7 percent in FALAH 2012.

Ideal Number of Children

Although individuals’ fertility desires and intentions may vary among men and women, convergence between husbands and wives is a prerequisite for converting intentions into behavior, as it increases the chances of translating desires into reality. Table 2 compares the level of convergence on the desired number of children among couples from the province of Punjab from 1991 to 2012. The Table also shows data from PDHS 2006-07 where women were asked their perceptions about their husbands’ desired number of children (although men were not interviewed). The Table suggests that the number of couples for which husbands and wives want the same number of children has increased. Another encouraging change is observed in the category where husbands want fewer children than their wives: it has increased from five to eight percent indicating husbands’ interest in having smaller families. In addition, according to the FALAH endline survey, about 18 percent of wives did not have a specific number in mind and/or were unaware of their husbands’ desired number. This proportion was almost double in 1991, so this change also suggests a gradual trend of increasing spousal communication. Overall, more than 52 percent of wives from the FALAH endline survey reported that their desired number of children was the same as their husbands and this number was reported to be higher in PDHS 2006-07. Of these couples, two-thirds desired four children or fewer (data not shown); this figure was 47 percent in the PDHS 1991.

Source: Pakistan Demographic Health Surveys 1990-91 and 2006-07 and FALAH Endline survey 2012

There was a wide divergence in reported ideal family size across regions. In the districts of Jhelum and Okara, the desired family size reported was lower at about two to four children as compared to the districts of Bahawalpur and D.G. Khan where a higher range of four to seven children was reported as ideal. Both men and women generally considered four or five children as constituting a ‘small family size’ in the latter districts. Overall, having four children was the considered ideal for the majority of the interviewed men and women. Furthermore, there was no difference in the ideal family size across urban and rural settings of both Northern and Southern Punjab.

“I think two children are enough; inflation is too high and expenses are not bearable.” FGD, Rural Okara
Interestingly, desired family size for women was higher than for men in all of the Punjab districts - a result similar to the FALAH endline findings. The main reason driving a higher desired number of children was the desire to have a son, or to have a pair of sons or daughters.

“My husband wants four children. He says that if God gives him one son, even that will be enough. I have three daughters, and I wanted two more sons.”
IDI, woman with 3 children, Rural Bahawalpur

Respondents also shared their reasons for their ideal family size(s) during FGDs and IDIs. Both male and female respondents desiring (perceived) smaller family size were driven by economic concerns.

“Islam generally advises you to spread your seed and have children. However, if we look at the conditions of a poor man, I would say that two to three children are okay.”
FGD, Rural Jhelum

The desire to provide good health, education, and other basic necessities to their children was a strong force leading to the desire for small families.

“Financial problems are a strong reason in the minds of people that convince them to try out family planning. Let us suppose that there is a small family comprising two children. They will only be able to survive if they earn 500 to 700 rupees daily. The other reason is education.”
IDI, man with 4 children, Rural Jhelum

While these views were generally shared by respondents from Bahawalpur and D. G. Khan, a few FGD respondents also justified their desire for more children on religious grounds. The concept of having a pair of boys or girls and having more children due to a fear of loss of any existing children was also reported by some respondents.

“I think children are blessings from God. I am in favor of having four to five children.”
FGD, Rural Bahawalpur

“Parents think their children would be a support in their [the parents’) old age. God forbid, if a person has only one child who becomes ill or has some problem/abnormality or dies, it would be very difficult for him to propagate his lineage.”
IDI, man with 2 children, Rural Okara

There was a divergence between husbands and wives regarding the desired number of children. In many cases, wives or husbands compromised their desire for more children on religious grounds. The concept of having a pair of boys or girls and having more children due to a fear of loss of any existing children was also reported by some respondents.

“Initially, it was two children [initial planned number of children]. But then the third one came along. It was my wife’s wish; she used to say that he did not have a brother [referring to the older son].”
IDI, man with 3 children, Urban Jhelum

“I think three children are enough. My wife wants to have one more child. She wants to have a couple of sons and daughters.”
IDI, man with 3 children, Rural Bahawalpur

The desire to complete a pair of boys or girls and family pressure from mothers-in-law and relatives were also mentioned as reasons for the differences between actual and ideal family size.

“When alone, even a tree does not look good. One should have at least a couple of brothers who can share happiness and sorrows [dukh such]. And one should also have at least a couple of sisters who can share happiness, sorrows, and others’ problems.”
FGD, Rural Bahawalpur
“We wanted only two children but ended up with four because of my mother-in-law. After having three children my seven-year old daughter used to weep about not having a sister. Even though we were using condoms at that time, one got ruptured, and I became pregnant.”  IDI, woman with 4 children, Rural Okara

“I have two daughters and a son, so I would wish for another son so that I have a pair of each.”  IDI, man with 3 children, Rural Okara

Views on Family Planning: Gender Differences

Supporting the findings of the FALAH endline survey, a majority of male FGD respondents across the districts were in favor of FP. They commonly claimed that all men talk openly about issues pertaining to FP. This was especially evident when men spoke without hesitation irrespective of their rural or urban backgrounds. The FGD and IDI findings presented overwhelming evidence that adverse economic circumstances and an increasing level of inflation were the main reasons compelling men to think about and accept FP.

“Yes, the men are in favor of family planning. Since the condition of our country is very bad, men are compelled to think that there should be fewer children.”  IDI, woman with 4 children, Rural Okara

During an IDI, a respondent shared his own views about other men in the community.

“I have not seen anyone against it so far. In these circumstances, men are mostly in favor of birth spacing. My friends also have the same opinion and they say that it is better to have a gap between births. And since girls nowadays are also well aware and educated, they know the benefits of birth spacing. Not only is it beneficial for me, but also for my other half.”  IDI, man with 1 child, rural Okara

Different Motivating Factors for Men and Women

Given that both men and women appeared to be concerned about fertility issues (as the previous discussion suggests), it becomes important to examine the difference in factors that motivate them to consider and initiate these discussions with their spouses. Concerns about poverty were mentioned as major motivating factors in almost all districts by both men and women for at least temporarily limiting family size and adopting contraception.

“Poverty is the major motivating reason. You must have seen that it is difficult to afford more than two kilograms of flour. I am just a laborer, so my income is quite low. Income levels are not proportionate to the level of inflation. How are we going to feed ourselves if we have a large number of children?”  IDI, man with 3 children, Rural Bahawalpur

Rising inflation and expenses of rearing children and their schooling also emerged as important motivating factors for both men and women across the districts.

“One needs to take care of the children as well, and that is obvious. It is no use giving birth to children if you cannot bring them up properly.”  FGD, Urban Jhelum

“People think if they have a larger number of children, they will not be able to provide them with good educational opportunities and also, they will not have a chance to raise them with a good living standard.”  FGD, Urban Bahawalpur
The children I already have are enough (five). They will get a good education that way. There are problems associated with education. After all, children incur expenses. They will have a good education, and if you have a moderate number of children, it becomes easier to handle them - it is easier to bring them up. Everything becomes easier. The more children you have, the greater the extent of division in your property. These problems carry themselves with you for the rest of your life.” 

IDI, man with 5 children, Rural Okara

Maternal and child health were mentioned more by women but also by men as a motivation for FP.

“In poor households, women do not have much food to eat to ensure their own health. When a woman produces two or three children, she becomes weak and fragile. In the end, she thinks about sterilization; that it is the solution not only for her health, but also for her children’s health and their upbringing.”

FGD, Rural D.G. Khan

Child rearing and women’s health concerns were mentioned more by men during the IDIs stating their own realities. For example, a male respondent mentioned how his wife had convinced him to use FP by expressing her concerns:

“She used to talk about routine matters; the children’s cleanliness, bathing them, putting them to sleep. She said she was sleep deprived because of the children. When my wife got fed up of looking after the children, dressing them properly, ironing their clothes, maintaining the house, and keeping them (the children) clean and neat, she used to tell me that we should stop having children.”

IDI, man with 6 children, Urban D. G. Khan

The role of relatives (other than the husband) such as the mother-in-law and other kin was also mentioned as an influence on decisions regarding family size in rural communities.

“Social pressure comes mainly from relatives. They will consider themselves socially stronger if they have more children, and will have an upper hand and look down upon you.”

FGD, Urban Okara

Continuation of the lineage through sons was another driving force for having more children.

“I wanted about two or three children. We have tried a lot, but these things are not in our control. Now we have five daughters. Yes, there is a specific pressure within the household. My brother recently had a son and now my parents have started discriminating against me and taunting me (that my brother has a son and I do not).”

FGD, Rural Jhelum

“There is another pressure, that if a couple has a first child and it is a daughter, then they will continue to produce (four to five) children until they have a son. ... In my neighborhood, a couple has six daughters and all of them were conceived with the hope of a son. They say they will stop having children as soon as they have a son.”

FGD, Urban Okara

Initiation of Discussion About Family Planning Use

The aforementioned motivating factors compel men and women to think about their fertility intentions. Their intentions cannot be converted into behavior unless they talk about it with their spouses. The FGDs and IDIs suggest that communication does exist between spouses about family size and contraceptive use in all districts, although there was a mixed response about the initiation of communication, either by husband or wife. The nature of this response varied through districts as well.
as urban and rural settlements. Most FGD respondents and a few IDI respondents mentioned that women usually initiate the discussions about the determination of FP or use of contraceptives. It was also mentioned by both men and women that it is women who are more concerned with family size and the use of contraceptives because the burden of child rearing falls mainly on women. Secondly, they have the added responsibility of managing the household with limited economic resources, and thirdly, they possess a greater realization about the significance of these issues as a result of female-focused interventions.

“My wife started this discussion about family planning because she no longer had the will to bear more children at this point and said I should use the withdrawal method.” IDI, man with 1 child, rural Bahawalpur

“I initiated the discussion. I think women initiate the discussion because they know that they have to run the house and manage food and clothes for their children. The woman takes care of these things; men just earn.” IDI, woman with 3 children, Rural Jhelum)

“My wife initiated the conversation and I agreed with her as we have limited resources.” FGD, Urban Jhelum

A considerable portion of respondents say men start the discussion. A majority of men and women from IDIs stated that men initiate discussion on family size and contraceptive use because the responsibility of earning falls on men. Secondly, only men make decisions on household matters in male-dominated societies.

“I started the discussion with my wife about the number of children because I have to bear all the expenses.” IDI, man with 3 children, Rural D. G. Khan

“It is a male-dominated society. Women do not have any say in decision-making.” FGD, Rural D.G. Khan

“The man guides the woman in this situation. He takes her into confidence by discussing the issue with her.” FGD, Urban Bahawalpur

The third opinion emerged from the FGDs, which stated that either the husband or the wife can initiate the discussion; the person who suffers or experiences more problems takes the lead; it also depends on awareness and exposure. According to several respondents, it does not matter who initiates the discussion, because it depends on the level of concern and severity of the issue. Men take the initiative if economic concerns are strong, and women initiate the discussion if there is a serious health concern or there is an issue with taking care of the children or household responsibilities.

“Couples automatically start thinking about family planning after the first child if they are sensible and educated. People should have a planned number of children even if they possess (ample) resources. If a man wants to ‘tease’ his family, he will have many children. Otherwise, he will think about family planning (The respondent used the word ‘tease’ to imply someone causing discomfort).” FGD, urban Okara

“A husband initiates the topic if he gets tired and thinks he is unable to meet the expenses of the household. A wife initiates the conversation if she gets tired and cannot take care of the children. These are the two common situations (which motivate people to initiate such discussions).” FGD, Urban Bahawalpur

Although few in number, some respondents from D.G. Khan (3 FGDs) and only one female (IDI) in Jhelum also mentioned that educated couples and those with greater awareness are more concerned about family size or birth spacing and are more likely to discuss these issues with each other.
“Those who are aware of family planning do discuss it. Some literate people think we need to give a ‘perfect product’ [educated children] to society; such people think about and discuss family planning.”  FGD, Rural D.G. Khan

“Both men and women have the faculty of thought and consider the fact that they want a good education and living standard for their children. Whoever [husband or wife] has greater awareness initiates the discussion.”  FGD, Rural Jhelum

A majority of the men and women in almost all places stated during the IDIs (males 9 of 26 and females 13 of 26) and FGDs (8 of 12) that they initiated the discussion about the issue of FP after having their first or second child. However, a few IDI respondents (6 of 52, men and women) from Bahawalpur, Okara, and Jhelum did say that they started discussing these plans just after getting married and even before the wife’s first pregnancy. One man from Bahawalpur said that his wife started using pills just after getting married in order to delay her first pregnancy and that it was done with mutual consent.

“Two days after we got married, we had a discussion about having children. We decided not to rush into it and wait a year. Then, we got pills from a local doctor. She [my wife] took three strips of pills for a gap of nine months. She started taking pills three days after our marriage.”  IDI, man with 3 children, Rural Bahawalpur

On the other hand, a limited number of men and women (4 of 52 IDIs) reported that they began the discussion on the issue of family planning or desired family size after having three or four children.

“We thought we should practice birth spacing [due to inflation] after the birth of our youngest child [the fourth child]. That is why we are now using condoms.”  IDI, man with 4 children, Rural D.G. Khan

The combined responses suggest a pattern: women and even men are now concerned and plan their fertility even at the beginning of their marital life. Though the gap between fertility intention and behavior is wide due to many factors, they have started being more concerned and discussing these issues.

“My wife mentioned that our child was only two and a half years old, and still young. I told her that it was up to her [to use FP methods]. I stayed for two to three months, and then returned after another one and a half to two years [abroad]. This is how a gap of four years was maintained. It was my wife’s desire to increase the gap a bit.”  IDI, man with 3 children, Urban Jhelum

**The Road to Contraceptive Use**

Further exploration was required to assess whose thoughts dominated the final decision, and how long it took to actually start using contraceptives. By and large, men in both FGDs (6 of 12) and IDIs (4 of 26) admitted that despite living in a male-dominated society, women were often successful in convincing their husbands of their own (women’s) desired number of children and contraceptive methods in cases where couples’ thoughts differed. Men further explained that it was not easy for them to agree, but that women eventually manage to make their husbands agree with them. The discussions also suggested that if women keep on repeating their point of view, men eventually agree.

“For two months, she kept on disturbing me by being angry, beating the children, bad cooking, and irregularity in performing household chores. Finally, she made me agree and I permitted her to get sterilization.”  FGD, Rural Bahawalpur
Men also reported that the number of living children (particularly sons) also makes women stronger and empowered because children are considered a guarantee against being thrown out of husbands’ houses.

“I told my wife she must not get sterilized. She said she would go to the hospital for the procedure anyway. Then I threatened to marry another woman. She said it would not matter to her as she already had children which are blessings from God. She gave me permission for a second marriage because she knew she had children for support.”  FGD, Rural Bahawalpur

The majority of the IDIs demonstrated that wives convinced their husbands to use contraceptives. There were two interesting cases from D.G. Khan where men reported that their wives did not even inform them before using contraception. A respondent’s wife consulted her cousin and started using injectable contraceptives without informing her husband. In the other case, the wife informed her husband after having herself sterilized. These examples suggest that women can make independent decisions to use contraception.

“She did not discuss anything with me before sterilization. She got herself sterilized when she was at her parents’ home. After having the operation done, she called and told me that she had had herself sterilized. I said to her, ‘you should have gotten my permission and had a discussion with me.’”  IDI, man with 6 children, Rural D. G. Khan

“She consulted her cousin who is living here. He recommended the injection for my wife.”  [In this way, the decision to get herself injected was purely an independent one.]  IDI, man with 3 children, Rural D.G. Khan

The majority of women do require consent of their husbands to use contraception, however. In fact, without a husband’s agreement, access to contraceptives becomes even more difficult. In the majority of cases, discussions are usually initiated by women; they try to convince their husbands and mostly succeed. The discussions suggest that either women convince their husbands, or that contraceptive use is a mutual decision. Either way, the positive and supportive role of the husband is prominent.

“Without the consent of the wife, a man cannot do anything. If both agree, then they will use any method they want.”  FGD, Rural Bahawalpur

“I think women start it [discussion] first. So, you have to accept your wife’s demands. Women convince their husbands.”  FGD, Rural Okara

**Factors Impeding Men: Unmet Need for Family Planning**

The critical issue remains in cases where husbands are not convinced of the value of FP. A common situation was husbands’ disagreement or non-consensus on a particular contraceptive method as a barrier to FP. Moreover, religious concerns, particularly on methods used for family limitation, were also mentioned as barriers for FP.

The approval of FP does not necessarily mean all husbands will allow their wives to use contraceptives. In one of the FGDs in a rural community of Bahawalpur, husband disapproval was also mentioned as a barrier to the use of contraceptives as a birth limiting method. One FGD respondent elaborated:
“I have told you that the woman [neighbor] did not want to bear more children and wanted to get sterilized, but her husband warned her not to go to the hospital for sterilization. She discussed the issue with me and forced me [to take her]. Then, I took her to the hospital for sterilization [on a motorbike].”

FGD, Rural Bahawalpur

“My husband is not against family planning, but he does not like family planning methods [due to a fear of side effects].”

IDI, woman with 3 children, Rural Okara

Religion: In general, religion was not a strong constraint holding men back from FP use. Only a minority (2 of 26 IDIs with men and 3 of 12 FGDs) reported these views. One view was against modern contraceptive methods, while the other view considered FP to be against nature but a part of social practice and constituting a need. Interestingly enough, both respondents who expressed these views were currently using FP themselves. One was practicing the withdrawal method and the other’s wife was using injectable contraceptives.

From the point of view of women, two respondents from D.G. Khan and Okara reported that their husbands were not against FP, but were against modern methods. This includes sterilization in particular, which is considered to be against their religion.

“I think that FP is against the laws of nature. However, you can say that using contraception has more to do with social norms [dunyadari].”

IDI, man with 6 children, Rural D.G. Khan

“My husband says that you can use any method but sterilization as it is a sinful act.”

IDI, woman with 6 children, Rural D.G. Khan

Similarly, it was mentioned in a rural community of D.G. Khan that men are against FP on religious grounds. However, it was stated in later discussions with men in this community that a considerable number of men and women were practicing FP. During these group discussions, men sometimes shared the views of others who were not in favor of FP.

“People think that newborns bring bread and butter with them. You were not able to earn when you were a child but even then, you have grown up. Similarly, these children will also grow. Why should we stop child bearing—it is a sin. People argue that children should be produced. It is interference with nature to prevent fertility.”

FGD, Rural D.G. Khan

Family planning services: There are other reasons cited for not using contraceptive methods which include the non-availability of contraceptives, experienced and perceived side effects of contraceptives, contraceptive failure, and contraceptive costs. Men mentioned that with the exception of LHWs, there is no source of information for them at the community level. According to a few FGDs as well as IDIs, in recent years, the involvement of LHWs in the polio program has diverted their attention and rendered them unable to perform their primary duties as LHWs.

In two FGDs (urban D. G. Khan and rural Bahawalpur), the discussion centered on the point that most contraceptive methods are for women and thus the burden of use is on women. Secondly, it was stated that all interventions for FP are aimed at women, as a result of which husbands remain largely unaware and cannot take any initiative themselves. In addition, they do not value the information their wives give them. The respondents further explained that due to men’s limited knowledge of methods, arguments arise between husbands and wives about contraceptive use.
“There should be a man who takes the initiative to start discussions and give information about family planning. In our houses, there is usually a clash of opinions (between a husband and a wife on contraceptive use) because the wife has a better understanding of family planning thanks to the LHWs; men have no such knowledge.” FGD, Rural Bahawalpur

Issues of uneven contraceptive supply at the community level also came up as a barrier in two communities of Bahawalpur, one urban community of D.G. Khan, and one rural community of Okara. According to community members, the diversion of LHWs’ scope of work from FP services to the polio campaign has presented the non-availability of contraceptive methods as a barrier. Non-availability of contraceptives at nearby static health facilities also emerged as a barrier.

“After the birth of my third child, I asked my husband to use something (family planning method). He refused (he did not want to use condoms or withdrawal and was also against female sterilization) and asked me to use a method instead. Then I asked an LHW to provide injectables but she said she received just one injectable every month and had already given it to someone else. I tried the hospital (BHU) three times but they said they were short of injectables and/or syringes. I could not go there again as it is hard to leave house and there is no one to accompany me. (As a result) I am pregnant again (currently pregnant). Methods should always be available at hospitals so that women never find themselves in these situations.” IDI, woman with 3 children, Rural Okara

Side Effects

Experienced or perceived side effects were highlighted in all FGDs and most of the IDIs, both in urban and rural settlements as barriers to using contraceptives. Male respondents stated that methods such as pills, injectables, intrauterine contraceptive devices (IUCDs), and female sterilization all have severe side effects for women. Irregularity in the menstrual cycle, obesity, and anemia were commonly mentioned.

“Women face bleeding problems due to the injection. After a month, the menses cycle is natural, but the injectable disturbs the menstrual cycle. It is very threatening for a woman.” FGD, Rural D.G. Khan

“She (my wife) faced severe prolonged menstrual problems and it affected her health. She was not in good health very often then.” IDI, man with 6 children, Urban D.G. Khan

“My friend’s wife used an injectable to avoid unwanted pregnancies, but was surprised to find her pregnant some days later. He now believes all such things (contraceptives) are ineffective.” FGD, Rural D.G. Khan

A few respondents also mentioned the cost of managing the side effects of contraceptive methods. Participants said the whole experience is useless if they use FP for economic concerns in the first place, and despite that, they have to bear a heavy cost for the treatment of side effects.

“People faced side effects after using various family planning methods and cannot afford the cost for side effect management. People believe that family planning can lead to many diseases.” FGD, Rural Bahawalpur
Readiness and Receptiveness of Men Towards Male Focused Interventions

Background

The FALAH project was designed to tackle the major obstacles leading to high levels of unmet need and low FP use in primarily rural areas across the four provinces. Among the major initiatives included in the Communication and Mobilization strategy was the focus on addressing men and husbands as primary audiences, given that they are major influencers both at the community and household level. The strategy utilized both mass media and interpersonal communication to provide information to men and to mobilize them to use FP services. In addition, the indirect influence of RLs on men was utilized through the training of local *pesb Imams* to include messages in Friday sermons.

Effect of Male-centered Interventions on Fertility Intentions and Behavior—Evidence from FALAH

It is important to triangulate findings from the qualitative study with the quantitative evidence from the FALAH baseline and endline evaluation looking at the impact on attitudes, approval, and behavior of individual male interventions. The results suggested that interventions in general and male-focused interventions in particular, played an important role in shaping the fertility behavior of couples.

The results include insights and evidence comparing the impact of interventions addressed at women (which enable them to communicate better with husbands), interventions directed through the mass media at both men and women, and above all, interventions addressed at men alone. This will guide the scope of future communications and service delivery programs.

Table 3 (page 19) shows an overall increase in the acceptance and approval of family planning in a span of four years. MGMs seem to be highly effective in increasing approval of FP by men. Unfortunately numbers of men in MGM was small. Group meetings for women and visits by LHWs also proved to be agents for changing couples’ approval of FP. On the other hand, interventions through the media or RLs’ sermons did not contribute any notable change in couples’ perspectives on FP. These findings concur with the overall findings of the FGDs and IDIs which strongly endorsed group meetings and person to person interactions to gain family planning approval and to spread information.
### Table 3: Change in couples’ approval of FP before and after FALAH interventions (Punjab districts)

Table 4 (page 20) shows the change in the desire to have more children between the baseline and endline surveys. It is encouraging that a decline in the desire to have more children was noted in all groups. Analysis of the contribution of interventions suggests that MGMs proved to be highly effective in changing the behavior of men and ultimately helped couples limit their family sizes as compared to those who did not attend these meetings. Secondly, the MGMs and attendance at Friday religious sermons also played an important role in lowering the desire to have more children among couples. In contrast, media interventions, particularly television, did not impact the desire for more children among couples. This again concurs largely with the qualitative findings.

The comparison of the baseline and endline data in Table 5 (page 21) clearly shows a strong impact of FALAH interventions on the contraceptive usage of couples. The role of interventions such as MGMs in increasing contraceptive use was very strong; this reinforced the resounding need expressed in the FGDs and IDIs for avenues through which men could get direct information in a group setting.

Source: FALAH baseline survey 2007 and endline survey 2012.

The qualitative study was designed to examine some of the responses to these interventions in three FALAH districts of Punjab and to explore what men require in the way of interventions directed at them. Similar questions were probed in Okara where there were no such interventions.

Further exploration of the role of interventions, particularly those that were male-focused, emerged as a main objective of the qualitative study. Therefore, local perceptions and suggestions were directly sought about different types of interventions from both men and women during the FGDs and IDIs. The specific focus was to assess the relative utility and impact of MGMs and the involvement of RLs and media campaigns. Moreover, any additional suggestions from men and women were also explored.
Men’s Readiness to Be Involved in Family Planning Programs

First of all, it is worth restating that most men (in 4 of 12 FGDs and 22 of 26 IDI respondents) from all four districts expressed strong FP desire. Further, they stated the need to be involved in FP programs through interventions. They believe that women have been the focus of all interventions to date, which has no doubt raised their awareness regarding FP but has also shifted the entire burden of FP adoption and use to them. However, it is essential to involve men and to ensure that these programs are successful because men are the real decision-makers in this male-dominated society.

“Motivating men is like word-of-mouth marketing. If I have some information about family planning, I can transfer it to other people more easily than women can as they have limited mobility.” FGD, Rural D.G. Khan

“No matter how much a woman is motivated, there is no way she would willingly adopt family planning methods unless her husband agrees to it. A method can only be adopted when both concerned parties talk to each other about it.” FGD, Urban Bahawalpur

They also emphasized that such interventions require that a major knowledge gap on contraceptive methods be filled.

“A program initiated through men will be more effective. Seventy percent of Pakistan’s population lives in the rural areas. The remaining thirty percent resides in urban centers. Such programs can be initiated through men and women with the same kind of impact. But the same success in rural areas can only be achieved if men in those areas are properly motivated.” FGD, Urban Bahawalpur

Intervention Through Male Group Meetings

The majority of FGD (12/12) and IDI (36/52) respondents displayed a strong interest in intervention through male group meetings (MGMs). Variation across districts and rural-urban areas was negligible. However, perspectives and concerns varied across communities.

Even in Okara (a non-FALAH district), men, unprompted, mentioned the need for such meetings. According to almost all of them, MGMs were the best way to convey FP information to men. Most of the men stated that MGMs could be very helpful in passing on specific family planning messages.

“I think there should be a gathering of a large number of people and that they should be told of the threats of not planning their families. Many people feel shy attending small gatherings (or one-to-one meetings). You should arrange the meeting and brief them about the possibilities of threats and the cons of not practicing or listening to these instructions which are for their own benefit.” FGD, Rural Jhelum

“There should be separate meetings for men and women. They should be told everything about childbirth and spacing. They should be told about the different facilities and methods available for birth spacing.” FGD, Rural Okara

In most communities, men highlighted the importance of MGMs by comparing them with women’s meetings. According to them, MGMs could be more effective and beneficial as compared to women’s group meetings because women cannot do anything nor decide upon anything if the men are not convinced.
“There should be more meetings for men. A woman cannot do anything and is helpless. If there will be more meetings with men, this will be useful for their women as well. If you conduct a meeting once a month consistently, the message will gradually be conveyed effectively. Even if someone does not have any medicine, he can be prescribed that medicine which can be obtained from the market.”  FGD, Rural Okara

Similar to the responses from FGDs with men, the majority of men and women interviewed in the IDIs from all four districts were in favor of MGMs.

“Yes, we have a male-dominated society. The family planning program will yield excellent results and success via a men-to-men policy (men motivating men).”  FGD, Rural D.G. Khan

“The door-to-door approach is not possible in the case of men. There should be a separate place where meetings can be held to educate men. One man should deliver a lecture on the topic to a local gathering of men. People should be educated on this matter in the form of a group. It would be more effective.”  IDI, man with 3 children, Rural Bahawalpur

They were of the view that such meetings should be held in order to educate and motivate men since men generally lack knowledge on FP methods and do not know how or where to procure contraceptives. Moreover, they are the main decision-makers at the household level for many issues, including fertility.

“It is the male who has the decision-making power in our area. Women are not heard from until their husbands are convinced.”  IDI, man with 6 children, Urban D.G. Khan

Men from Bahawalpur and D.G. Khan also expressed the view that public gatherings/MGMs would be effective for people who did not have access to FP information, and that it would propagate awareness among the male population. These views were mentioned repeatedly by male respondents in each district during IDIs. This general perception about the success of MGMs was also endorsed by male respondents who had already attended such meetings under the FALAH interventions.

“These meetings proved to be very helpful. My husband’s views were different after attending the meeting. It was very helpful for us, and we learnt which methods were easy to use. Therefore, we discussed it with one another.”  IDI, woman with 3 children, Rural Jhelum

“These meetings are very helpful for men. They (the hosts) put forward suggestions in the meetings. They also told us about different methods and how to use IUCDs and condoms. Some people learnt the entire procedure from them. My husband’s views were different after attending the meeting. We knew which method was easy to use.”  IDI, woman with 3 children, Rural Jhelum

Proposed strategy for male group meetings

Respondents were asked about the ideal strategy for holding these meetings, including how they should be organized, who should conduct them, and potential outcomes. The most prominent suggestion during the FGDs with men was to hold these meetings on a regular basis. In the IDIs, men (20/26) further suggested that meetings be organized near their localities or within their villages so that everybody can participate easily. Men were quite specific and suggested men gather at a pre-determined place to discuss the importance of FP and BS.
“There should be a work plan according to which it must be announced that a meeting will be held at a specific time and place, where a man would deliver a lecture on family planning and the various issues pertaining to it.”
IDI, man with 3 children, Rural Bahawalpur

“The whole point is managing the population. Instead of conducting the meetings in their offices twice a week [referring to the Family Welfare Center in the area], they should do the same in some village. There should be a list telling them that the meeting next week will be in the village so and so. They should proceed by putting a ‘manji’ at the center of the ‘chowk’.”
IDI, man with 7 children, Rural Okara

In comparison, both men and women from the urban areas of Jhelum district emphasized the need for having female group meetings (FGMs) parallel to the MGMs to promote couple communication. According to several respondents, even though male meetings are very important, there should be group meetings for women as well. This would simultaneously bridge the gap of communication and decision-making among couples.

“It would be easier for women who cannot convince their husbands if there is a meeting for men on one side and a meeting for women on the other.”
IDI, woman with 3 children, Urban Jhelum

“There should be a program which can be introduced for (both) men and women as this problem is faced by both sexes. There would have been no need to ask anyone had it been only one gender’s problem.”
IDI, man with 2 children, Urban Jhelum

In response to the question “who should conduct these meetings?” the majority of FGD and IDI respondents from all districts suggested community-level meetings be organized and facilitated through local people as they know their communities better and people trust them.

“A local person needs to be hired to cater to the men’s needs. There should be a meeting once a month or once every two months.”
FGD with rural men, Jhelum

“The team should comprise outsiders, but there must be one representative from our village because people trust local persons.”
IDI, woman with 4 children, Rural Okara

Respondents did, however, feel the need for an educated outsider to conduct the meetings.

“Ideas of people, who belong to same community, are similar. That is why a person who comes from the outside will be able to educate the people in a better manner. It would have an effect.”
IDI, woman with 3 children, Urban Jhelum

Generally, male doctors were considered ideal for conducting such meetings as community men would trust such a knowledgeable person. In addition, men can also share their FP and general health-related issues with doctors.

“Your strategy of coming here and briefing me on family planning should be done everywhere. By this, I mean that I will go to my friends/peer group and gather them in the town to convey your message. I will also refer to you for proper guidance. This will prove to be beneficial for you as well as the government. This is how campaigners can garner a good response.”
IDI, man with 6 children, Urban D.G. Khan

“A more effective thing will be making the people understand/telling them. Since most people listen to doctors, it would be more effective (to involve doctors).”
IDI, woman with 1 child, rural Bahawalpur
“Education is obtained by almost everyone, but a proper training and education on this matter (family planning) can only be provided by the department or doctors.”   FGD, Urban Okara

Another important suggestion that emerged from the FGDs (6 of 12) was that only raising awareness and providing knowledge on FP would not be sufficient; these doctors should provide contraceptives on the spot as well. They believed not supplying contraceptives would allow the chances of laziness to take over, preventing men from buying or accessing contraceptives themselves later.

While talking about possible incentives for men to attract them to the meetings, male respondents generally stated that medicines and some kind of refreshment should be provided. Overall, they suggested that the meetings should be informative and interesting so that men can be attracted to them. Most of the women considered knowledge and information related to FP techniques to be sufficient incentives in themselves for male participants.

“These meetings are very important. If they [men] do not gain any knowledge about family planning, how can they practice it? My husband, for example, does not know anything about IUCDs and admits it. If men are told about contraceptive use and the various methods, then their minds can be changed. They will think about it.”   IDI, woman with 2 children, Urban Jhelum

“Medicines should be given and the procedures should be accounted for (details about the procedures should be given). Providing food, however, is a separate issue.”   IDI, man with 7 children, Rural Okara

Some male respondents agreed and said the main incentive of going to MGMs for males was information and awareness.

“Without the motivation and awareness of the man, a woman cannot pursue the family planning program successfully. For example, LHWs can tell only women about birth spacing. She [the woman] can use family planning secretly without her husband’s permission. That is why the need of the hour is that men should also be motivated and convinced about family planning. It will be more effective then. So, a man can convince another man properly about using family planning methods.”   IDI, man with 6 children, Urban D.G. Khan

**Potential benefits of male group meetings: women’s perspective**

Generally, women voiced strong opinions about the potential benefits of holding MGMs. According to them, male-directed meetings would be very effective and would lead to a positive change in the mindsets of men regarding FP. Women mentioned that the main benefit would be that it would eventually become easy for wives to discuss FP with their husbands and convince them of their merits. Women in Bahawalpur considered these meetings to be a source of knowledge sharing.

“Meetings should be arranged for both men and women. But meetings for men are necessary. For example, if my husband listens to someone talk about these things, he will go and discuss it with another man. It will have an effect. It might not come to his mind directly, but at least he will know that the meeting was held and will go and tell a third person. I think that it is better this way and that these [meetings] should be organized.”   IDI, woman with 3 children, Rural Bahawalpur

Women from Jhelum stated that MGMs will also be helpful for those men who consider FP to be against religion. Their misperceptions will be addressed and they will be compelled to think about using FP.
“These meetings should be effective for men who consider family planning to be a sin. Their minds could change. There should be awareness for such men. If men are made aware, there would be less population, and they will think over it.”  
IDI, woman with 3 children, Urban Jhelum

If men are convinced and educated on FP, it would sort out half the problems that women face. They (the husbands) will realize the effectiveness and benefits of FP and allow the women to visit the relevant facilities. These meetings will raise awareness levels and help people understand FP.

“There is a general hold of men in our society. Women cannot do things without the permission of men. Since men play an important role, everything will be fine if men are convinced.”  
IDI, woman with 1 child, rural Okara

**Potential benefits of male group meetings: men’s perspective**

Men’s perspective in this regard was also important and men from every district during the FGDs (8 of 12) and IDIs (22 of 26) expressed their perceptions and understanding about the outcomes of MGMs. Men generally considered the venture beneficial.

“It is our opinion that a man will convey the message to ten people and the ten people will convey the message to a hundred people. In this way an ‘awareness chain’ will be created and it will be easier for your motivators to convey their messages.”  
FGD, Urban D.G. Khan

According to them, MGMs will prove to be a source of knowledge and information for men and as a result, not only will they be able to initiate the discussion with their wives, but also be convinced of the merits of contraceptive use.

“Group meetings are better as they produce better results. Meetings for men will lead to fewer children being born. People will get more information about family planning and refrain accordingly. Men will also be inclined to go home and talk to their wives about it, willing to take the first step. Out of the 50 percent who go home and talk to their wives, 60 percent will actually use them. It should make a difference.”  
IDI, man with 4 children, Rural Okara

This effect can help poor people have as many (or few) children as they can support according to their resources.

“The people who are overburdened would of course accept it. The poor would appreciate this sort of education because it provides a solution to their misery. There are two or three men in this locality who want to get themselves sterilized because they already have nine or ten children and cannot afford more.”  
IDI, man with 6 children, Rural D.G. Khan

Interestingly, some men stated that there would be less conflict between husbands and wives because men who were not ready to use any method earlier will try to use FP after attending these meetings.

“In my opinion, if men discuss [or initiate discussions] about family planning, it would be easier for women to convince their husbands because both would have knowledge about family planning. In this way, they would agree with each other quicker and decision-making would be faster as the wives would get information from the LHWs and the husbands from group meetings. It will make decisions easier and prevent unnecessary quarrels. Yes, in this way there will be equality in their thinking which can lead to easy decision making.”  
FGD, Urban Okara
**Intervention Through Religious Leaders**

Religious leaders (RLs) are believed to be respectable figures, highly knowledgeable in religious matters, and considered an authority on most issues. People also seek help from RLs in many family matters, including health issues. RLs are also consulted during decision-making, especially if an issue is considered to be controversial from a religious point of view. If the RL of a community declares an act permissible, everyone agrees to follow it. The use of FP is also sometimes considered to be against Islam. At this point, if RLs convey a message that contraception is allowed in Islam, people can use it more confidently.

The practicality of interventions through RLs was also discussed during FGDs and IDIs in rural and urban settings. This included perceptions about the involvement of RLs and the feasibility and benefits of involving them to increase contraceptive use; there was a mixed response across the districts.

Generally, men and women from all districts mentioned the social acceptability and respect for RLs in their communities. During FGDs in Bahawalpur, an extensive debate was held on the involvement of RLs in creating awareness and motivation about FP. Almost all respondents were in favor of the view that interventions should be made through *Ulema*. However, a few respondents stated that they should not use loud speakers for this purpose and should instead talk about such matters in private settings.

> “People should be convinced on religious grounds because a layman thinks a soul that has been destined to come into the world will come. He says that you [the person who tries to convince him about family planning], God forbid, consider yourselves gods and that you are asking me to stop a soul entering this world. Thus, there should be a counter argument against this view in light of the Shariat [Islamic code]. Religious scholars should disseminate this knowledge from a Shariat perspective.”  
> FGD, Urban Bahawalpur

Respondents from D.G. Khan stated that RLs can address the issue during sermons, but it was also mentioned that as a very limited number of people visit mosques or *maulvis*, they cannot approach every man in the community.

> “Maulvis can only speak to people who visit mosques. They cannot communicate their message to the entire populace of the area.”  
> FGD, Rural Jhelum

In the context of the perceived benefits of involving RLs in FP intervention, respondents mentioned that the involvement can generate awareness among men. They emphasized that a RL is more influential and his words carry more weight as compared to any other person. Interestingly, women were more vociferous than men in mentioning the potential benefits of this intervention. Women from Okara district were particularly vocal on the topic.

> “The maulvi’s word has an effect on people. In fact, it will be more effective if the (programs) are conducted through maulvis.”  
> IDI, man with 4 children, Rural Okara

> “It would be useful because when religious leaders gather people, people listen to them.”  
> IDI, woman with 3 children, Rural Bahawalpur

> “It would be beneficial when he [the religious leader] talks about the topic from an Islamic perspective. People obey them because religious leaders help distinguish between right and wrong and legal and illegal. I think that religious leaders can play a vital role in this respect.”  
> IDI, woman with 2 children, Urban Jhelum
However, the majority from all four districts was not in favor of interventions through RLs and had four sets of reservations. Foremost was the perception that these leaders are against FP and that their belief is to support more children. Therefore it was questionable as to how they can talk about small families. This notion was reported mainly by the men of D.G. Khan and Bahawalpur during IDIs.

“I think religious leaders will never say that there should be fewer children. They say, “According to the orders of God, family planning is not the right thing to do” (Aap jo mansoobabandi karty ho, woh Allah Talha kay hukam kay mutabik theek nahi hai) (IDI, woman with 2 children, Urban Bahawalpur)

“If someone goes to a religious scholar and is told not to produce children, he would obviously think that life is given by Allah. What kind of scholar would say that?” (IDI, man with 4 children, Urban D.G. Khan)

“The maulvis say that children are a blessing from God and that contraception is equal to murder. That is their opinion” (IDI, man with 4 children, Urban Okara)

The other dimension was the perception on the possible reaction of the community on involving RLs in FP interventions. They thought that members of the community would not accept RLs in this role and would count it as his “bad” deed. This was reported mainly in FGDs in Okara, D.G. Khan, and Bahawalpur.

“People will have objections. They will say that the maulvi receives bribes [rishwat]. The people will not like it if a maulvi talks about these matters after the Friday prayers [Namaz Juma] in an open congregation [yeh keya shuro ker deya hai].” FGD, Rural D.G. Khan

“He cannot do so. He only gets one day in a week to preach [Friday], and if he starts talking about this topic after seven days, the people will make sure that he does not come back to the mosque again!” FGD, Rural Okara

“They surely listen to him. But people do not like this type of talk at the mosque. Society is like this. There should be a program like group meetings.” FGD, Rural Okara

The third reason emerged from respondents in Jhelum. According to them, since contraceptive use is more of a young man’s domain, and since RLs are usually older men, the generation gap can act as a barrier to communication.

“Obviously if the maulvi is older, people will feel ashamed talking to him and discussing such things with him. [So, there should be younger mobilizers.]” IDI, man with 3 children, Rural Jhelum

Another reservation from urban Jhelum was that young men do not value RLs nowadays, so RLs’ involvement would not be effective.

“I think that it is difficult to accomplish it through a maulvi. Maulvis do not agree with it; it is as simple as that. As far as the briefing is concerned, they are not convinced much or in favor of family planning, in my opinion. The youngsters stay away from maulvis. The reason for that is that some people do not usually consult elders.” IDI, man with 3 children, Urban Jhelum

**Potential benefits of involving religious leaders**

On the other hand, quite a few respondents (18 males and females of 52 IDIs) showed a positive response to involving RLs in FP interventions, especially in Jhelum and Okara. One female respondent said that meetings for *maulvis* would be more effective and beneficial for the community because they are respectable people and have a special place in the community.

> “Religious leaders have a high social status in villages because people are uneducated. They do not have knowledge, and they consider a religious leader to be a wise man because he is associated with religion. That is why people obey religious leaders.”  
> **IDI, woman with 1 child, rural Okara**

> “The cleric’s words carry more weight than the Prime Minister’s. The cleric should deliver a speech at least three times a month on this topic according to the Quran and Hadith so that people can be educated and motivated.”  
> **FGD, Rural Jhelum**

Another woman explained that members of the rural community relied on *maulvis*, especially when it came to health-related issues. They went to *maulvis* whenever their children had health problems:

> “These people are most effective. The people of our village obey religious leaders even more than doctors. They take them to religious leaders when their children are taken ill.”  
> **IDI, woman with 2 children, Rural Okara**

Respondents in favor of involving RLs in FP interventions discussed suitable strategies to make RLs’ involvement effective. Since men and women from Jhelum and Okara during IDIs were generally more in favor of the role of RLs than respondents from D.G. Khan and Bahawalpur, most of the suggestions came from them. The respondents said RLs should be counseled and trained on the issue and that they should talk about it at Friday sermons.

> “It will be beneficial if the maulvis are trained and counseled. However, they might not agree to it.”  
> **IDI, man with 2 children, Urban Okara**

A woman from Okara (where there were no FALAH interventions) also suggested RLs give a speech after every prayer. One of the main suggestions was that RLs should discuss FP with the community’s men with reference to the *Sharia, Quran, and Hadiths* to make the intervention more effective.

> “I think the maulvi of a village should deliver a speech on these issues in light of the Quran and Hadith. As he is a religious scholar, he would have a strong impact on the people of the community and they would obviously follow him.”  
> **IDI, man with 2 children, Rural Okara**

> “The cleric is more influential in persuading any person; one will always prefer the words of a maulvi sahib to those of any other person [health worker, friend, or a neighbor]. So, a religious leader is important in convincing any person, if necessary.”  
> **IDI, man with 3 children, Rural Jhelum**
Media Interventions

The next set of interventions discussed were media FP campaigns on radio and television. Discussions about the role of the media did not reflect any significant regional variations, but did vary by gender. Women expressed their perceptions and thoughts in more detail compared to men. A substantial number of women discussed the topic more enthusiastically and said the media could play a positive role in increasing awareness and knowledge among both men and women. Although these women were in favor of media campaigns, a few did express their concerns that current advertisements cannot be viewed properly in the presence of elders or children.

“Every home has a television. Dramas should be in the Saraiki language. They will understand. They will say that they are watching the dramas, and through the dramas, they can understand.” IDI, woman with 5 children, Urban D.G. Khan

“Men do not pay attention to the commercials on television. When I watch an advertisement, I ask my husband to look at it: ‘two children are enough.’ He just said that people have up to six children.” IDI, woman with 3 children, Rural Okara

Interestingly, there was a different response from men regarding the use of media for FP. Men overall, did not appreciate the idea of relying on the media for interventions in the current study. This was quite different to what was reported by men in the PDHS 1990-91, where the majority of the husbands who had heard radio or TV messages about FP, perceived the media to be effective in persuading couples to use FP (NIPS-Macro 1992). On the other hand, respondents of this study mentioned that media campaigns were not effective because such programs could not be viewed in the presence of other family members.

Perhaps the discerning factor lies in the important point made during an FGD in Jhelum that, keeping in view the cultural context, programs with detailed FP messages cannot be covered on television or radio. Thus, media campaigns would have a very limited effect in giving direct information. They can create awareness about FP, which was more possibly the need in the 1990’s, but as mentioned earlier, men now require more detailed information on FP methods, which the media cannot address properly. Furthermore, and even surprisingly, a few men from D.G. Khan also claimed that poor people do not have access to a television and that is why these media campaigns cannot play a positive role. Evidently, two respondents from D.G. Khan also did not have the facility of television or radio in their homes.

“I do not have a television or radio at home. Sometimes I go out to read a newspaper.” IDI, man with 3 children, Rural D.G. Khan

“Television is not viewed by everyone. Many laborers who will have children, the people who process sugarcane and corn plantations, and people who farm potatoes; a lot of them probably do not have televisions. Poor people do not usually have televisions. These are the people who will bear the greatest number of children.” IDI, man with 7 children, Rural Okara

“I have seen advertisements for your pills in the commercial breaks between the dramas that are aired on television. There are boys and girls sitting around who are befuddled because of it. In my opinion, about 50 percent of society has been rendered corrupt because of this.” FGD, Rural Okara

“It cannot be properly portrayed by advertising on television and radio.” FGD, Rural Jhelum
A minority of male respondents did feel that the media could play a positive role; a few men from Bahawalpur and Jhelum stated they had learned at least something from television and that it could play a positive role in educating men.

“Televisions are better, because these days, everyone has a television.”
FGD, Rural Jhelum

“The media can play a better role to educate people about family planning.”
FGD, Rural Bahawalpur

Women were more explicit about the positive role of the media. A general reason for the lack of interest by men and women’s keen interest (particularly in television) may be associated with their presence at home. Women spend more time at home than men, and the television is women’s main source of entertainment; dramas attract them most. Women respondents generally believed that media can create awareness of FP methods’ advantages and can be a source of inspiration for their adoption by others. Women suggested a strategy involving media as an intervention tool:

- Family planning messages should be conveyed in proper drama serials;
- These drama serials should be telecast in local and regional languages, to make them more understandable;
- Recurring information on FP methods and messages should be shown on different channels.

“Dramas should be telecasted on the subject of family planning. These dramas should narrate a story that will compel people with many children not to have any more. The dramas should be in the Saraiki language.” IDI, woman with 5 children, Urban Okara

“Tell them through the television about how many children are ‘enough’ for them. Also, show them slides related to [the different] family planning methods. If a person is uneducated, his or her educated friends can read and tell them.” IDI, woman with 3 children, Rural Okara
Interventions for Men Through Community Health Workers

Lady Health Workers

In addition to the aforementioned proposed interventions, a few men and women also suggested other intervention strategies to increase FP knowledge and information in communities. First of all, most women commented on the performance of LHWs in their areas. Generally, men and women from Jhelum and D.G. Khan positively commented on LHWs. Men and women in Okara were not satisfied with their LHW services, however. Overall, a common complaint from almost all districts was LHWs’ constant involvement in the polio campaign, which compromised their role of FP service provision.

“LHWs’ scope of work has been confined to polio campaigns for many years due to which they neither visit women for FP motivation nor provide services at home. Secondly, they do not have contraceptive supplies on hand which diminishes their role anyway.” FGD, Rural D.G. Khan

“The polio teams (including LHWs and male mobilizers) come, give the drops to the children, and go away. If we want to ask them anything specific, they will tell us. Other than that, they do not provide any information.” IDI, woman with 4 children, Urban D.G. Khan

It was generally suggested that LHWs should concentrate on FP service provision and should be more knowledgeable and skillful for addressing women’s needs. They also mentioned that LHWs should be more educated and informative. In Okara, the fact that there are no other health services available in their area except LHWs was particularly mentioned.

“There should be a facility for us in the village. We do not have any facility. The LHW gets us free condoms, but she sells each for five rupees.” IDI, woman with 4 children, Rural Okara

“LHWs should be humble and polite. If they will not cooperate, people will question people’s need to go there [to the health centers, in the face of their non-cooperative behavior]. They should have a better attitude [to deal with clients].” IDI, woman with 4 children, Rural Jhelum

These suggestions indicate that women want greater reliance and utilization of existing sources of LHWs for the betterment of their communities. Some of the men also emphasized that LHWs must go door-to-door and brief every woman about the current population situation.

“I think that LHWs must go door-to-door and brief every woman about the current situation of the population and guide them on birth spacing and the different methods for this.” IDI, man with 2 Children, Rural Okara

Male health workers

Interestingly, during many FGDs and IDIs, men spontaneously compared the greater range of facilities available to women for FP in communities with limited facilities available to men.

“Just as there are LHWs, there should be male workers as well. They should debate with the men and have small corner meetings and should have materials and different services. Men should consult these health workers to acquire these services. I want these services to be available to men. It should be advertised that these materials are available from this specific center. Our women are Eastern, and they feel shy availing these methods. So, a man should be aware and he should acquire these methods.” FGD, Rural Jhelum
“In the same way as LHWs, there should be a male team for men that can gather them somewhere and guide them about what is better for them and how to use different [contraceptive] methods. Either that, or they can go door-to-door.”
IDI, man with 2 children, Rural Okara

Discussing, analyzing, and appreciating the program and the role of LHWs, the majority of the male respondents strongly suggested there be male health workers who provide services at the same scale as LHWs to men at the community level.

“In similar to an LHW who guides and discusses family planning with women, a man should be there to discuss, guide, and convince men about the importance of family planning.”
FGD, Rural Bahawalpur

Describing their role, they mentioned that they can provide counseling, arrange corner meetings, and provide contraceptives.

“There are some questions that a woman [LHW] cannot ask a man but a man can ask such questions from another man. Therefore, a man’s involvement in this becomes imperative. Men should join this field [as male motivators].”
IDI, man with 4 children, Urban Bahawalpur

Furthermore, men could avail the services of someone who can listen to them and manage their FP-related problems.

“Well, it will cause greater awareness. If you have a problem, you should know that there is a person who can be contacted.”
FGD, Rural Jhelum
Conclusions and Recommendations

This report presents findings from three sources, most of which are from primary data from the qualitative study in Punjab, along with secondary analysis of quantitative data collected in baseline and endline FALAH surveys; the third source is secondary analysis of data of PDHS 1990-91 and 2006-07 to see changes over time.

**There is a real change in men’s attitude towards family planning in the Punjab.** The study details men’s clearly articulated suggestions for their involvement in family planning programs, through increased access to information and services. Punjabi men appear to be more concerned about their fertility intentions and behavior than they were in the 1990s. Economic stringencies and inability to meet the household costs, including raising children, were men’s primary motivations for their approval of family planning. Both the qualitative and quantitative data confirm this change.

**Improvement in spousal communication has made it easier for wives to sway their husbands on fertility issues.** This study confirms widespread communication between husbands and wives on their family sizes and contraceptive use. While there are differences between men and women on desired number of children (higher for women than men in all districts), they do talk about this issue. As a result of their strong concerns, men sometimes initiate the discussion with their wives about their fertility intentions. This pattern suggests it is no longer the exclusive responsibility of wives to think and initiate family planning discussions. Due to both men’s and women’s emerging concerns, frequently they converge on ideal family size and contraceptive use. Among couples with a divergence of opinion, women try to convince their husbands after a series of discussions, as they cannot make independent decisions and their husbands are the ultimate decision-makers in all household matters.

**Regional differences persist in ideal family size, as reported by men and women.** The ideal number of children in Jhelum and Okara is lower than in D.G. Khan and Bahawalpur, reflecting established north and south Punjab differences. Moreover, there is always a difference between ideal and actual family size, the latter generally exceeding the former, due to a variety of reasons ranging from family pressure and couples’ own desires for ideal numbers of children for each sex.

**Supply side issues act as a barrier to using contraception for men.** Despite their positive attitudes towards family planning and frequent reported communication with their wives, a few factors inhibit men from use of family planning. Supply side issues are most frequently cited by men for lack of use, including lack of family planning services or contraceptives methods, along with method failure and contraceptive costs. Men recognize that their lack of knowledge about specific family planning methods is a barrier to contraceptive use. In addition, men voice fears of perceived or experienced side effects of modern methods along with lack of provider skills for managing these side effects.

**Men are highly enthusiastic about interventions employing male group meetings.** Despite their apprehensions, it appears that men are eager for male-focused interventions that increase their
involvement in family planning programs. Findings suggest that men and women in all districts show intense strong interest in the introduction of male group meetings as a family planning program intervention. Men especially see male group meetings as having potentially more impact than women’s meetings because it is suggested that it would be more effective to educate and pass on family planning messages to them rather than to their wives. A suggested strategy to conduct male group meetings includes involvement of a local or resident of the community to organize the meeting and an educated and skillful outsider (preferably a doctor) to conduct the meeting. The strategy also includes provision of contraceptives after the meeting to involve men in raising contraceptive use.

Religious leaders’ involvement a good source of support. There was a mixed response regarding the involvement of religious leaders in family planning programs; women being more in favor of this than men. Regional differences are also observed: men from Jhelum and Okara are more in favor of religious leaders whereas men from D.G. Khan and Bahawalpur did not particularly appreciate the idea. The ones who are in favor of involving religious leaders further suggest that they should be trained and they should talk about family planning with reference to the Quran and Hadith. The overall impression of the interventions through religious leaders suggests that they can and should play a supportive role by communicating the message that family planning is allowed in Islam.

Media plays a positive but limited role. Men were generally not very appreciative of the role of media such as television or radio in the effective communication of family planning messages. The reasons for this cited by male respondents were: lack of time to watch television, lack of availability of television (D.G. Khan), and the inability of television and radio to provide details on methods according to men’s needs. Women showed greater interest in interventions through the mass media and proposed telecasting of drama series on the topic in local regional languages.

Male health workers need to be involved to provide services. Men suggested that a male health worker on the lines of the Lady Health Worker program would be an ideal way of providing family planning services to men at the community level, much like Lady Health Workers cater to women.

Recommendations

This is an ideal time to carry out the following direct interventions aimed at men in Punjab since husbands are ready to be involved in family planning programs and are supportive of their wives using contraception.

- Interventions should be designed to provide information on the use and side effects of various contraceptive methods available to men.
- As a first step, group meetings or alternative channels of interpersonal communication should be organized for men. This type of intervention is essential to fill the gaps in men’s knowledge regarding family planning methods. The intervention would also help in eliminating fear of side effects, a big hurdle in sustaining contraceptive use.
- These interventions have to be backed by an improvement in the supply of contraceptives and family planning services in facilities nearby. Even in the context of male group meetings, the recommendation was that the meetings be combined with the provision of some supplies as well.
• In areas where there is a Lady Health Worker, men generally appreciated her work but the point was raised that Lady Health Workers had moved away from their focus on family planning. It is an important recommendation of the study that Lady Health Workers regain their focus on family planning, balanced with other priorities such as polio vaccine administration.

• An improved family planning service delivery environment is necessary, this was a demand voiced by men themselves.

• Additional interventions such as the training of religious leaders to encourage birth spacing and maternal and child health issues can have a positive influence as well. While this may not be carried out in each community, there are many settings where such an intervention is clearly helpful in clarifying men’s views on Islam and family planning.

Appendix B: Consent Form—In-Depth Interviews (Men/Women)

Greetings. My name is ________________. I am working with an organization called the Population Council that is helping the government of Pakistan improve health programs in the country.

You are invited to take part in a research study. Before you decide whether to participate, you need to understand why the research is being done and what it will involve. Please take the time to listen carefully as I read the following information. Please ask me if there is anything that is not clear, or if you would like more information. When all of your questions have been answered and you feel that you understand the purpose of the study, you will be asked if you wish to participate in the study.

We are interviewing men/women in your community regarding the decision-making process about reproductive health issues. We also need to know your views about involvement of men in FP programs through different interventions. I am here today to talk with you and you have been randomly selected from your community.

If you agree to take part in the study, you will be asked to give information about your own experience regarding reproductive health. Your participation will be voluntary and you will not receive any compensation/cash for participating in this study. It will take 30 to 40 minutes to complete the interview with you.

I am going to ask you some personal questions; you do not have to answer any questions that you do not want to answer, and you may end this interview at any time you wish. However, your honest answers to these questions will help us better understand the phenomena. Moreover, the information that is collected during the study will be kept confidential. Data will be stored in a locked cabinet dedicated to this study that only the study team can access.

If you permit us, we shall tape record the discussion for the convenience of retrieving the information easily in future. This tape will be confidential material and no one will ever be identified by name.

We would greatly appreciate your help in sharing your views for this study. It will take 30 to 40 minutes to complete the discussion. Are you willing to participate in the discussion?

Yes ☐
No ☐

Thank you for your cooperation.

Investigator or person who conducted informed consent discussion: I confirm that I have personally explained the nature and extent of the planned research, study procedures, potential risks and benefits, and confidentiality of personal information.

Name of person obtaining consent: ______________________________________

Signature of person obtaining consent: ____________________ Date:___________
Appendix C: Consent Form—Focus Group Discussions (Men)

Greetings. My name is ________________. I am working with an organization called the Population Council that is helping the government of Pakistan improve health programs in the country. You are invited to take part in a group discussion. Before you decide whether to participate, you need to understand why the research and discussion is being done and what it will involve. Please take the time to listen carefully as I read the following information. Please ask me if there is anything that is not clear, or if you would like more information. When all of your questions have been answered and you feel that you understand the purpose of the study, you will be asked if you wish to participate in the discussion.

We will have a group discussion with men of your community regarding decision-making processes about reproductive health issues. We also need to know your views about the involvement of men in FP programs through different interventions. I am here today to talk with you and you are randomly selected from your community for this discussion.

If you agree to take part in the discussion, we will ask you to give your views during the discussion. Your participation will be voluntary and you will not receive any compensation/cash for participating in this study. It will take 40 to 60 minutes to complete the group discussion.

You do not have to share experiences or views that you do not want to share, and you may withdraw from this discussion any time you wish. However, your honest answers to these questions will help us better understand the phenomena. Moreover, the information that is collected during the study will be kept confidential. Data will be stored in a locked cabinet dedicated to this study that only the study team can access.

If you permit us, we shall tape record the discussion for the convenience of retrieving the information easily in future. This tape will be confidential material and no one will ever be identified by name.

We would greatly appreciate your help in sharing your views for this study. It will take 40 to 60 minutes to complete the discussion. Are you willing to participate in the discussion?

Yes [ ] No [ ]

Thank you for your cooperation.

Investigator or person who conducted informed consent discussion: I confirm that I have personally explained the nature and extent of the planned research, study procedures, potential risks and benefits, and confidentiality of personal information.

Appendix D: In-Depth Interview Guidelines (Men/Women)

1. Did you ever go to school?
2. How many years did you go to school for?
3. How many children do you have?
4. What are their ages?
5. How old is your youngest child?
6. How long did you/your wife breastfeed them?
7. When would you like to have the next child if you want to?
8. How many children do you want in all?
9. Why do you want that many children?
10. What is your ideal family size and why is it so?
11. Have you ever talked to your husband/wife about the number of children that you want to have?
12. What is your spouse’s ideal family size and why does he/she think so?
13. Did he/she want to have the same number of children (as you did), fewer or more?
14. Why is there such a difference, if any?
15. Why didn’t you ever talk to your husband/wife about the number of children that you wanted to have (if the respondent never talked about it with his/her spouse)?
16. If you did talk, who initiated the discussion?
17. Did you ever try not to get pregnant while your child was (still) very young?
18. What did you do to avoid the early pregnancy?
19. Have you ever talked about contraceptive use with your husband/wife (detailed history of the communication process with reference to contraceptive use)?
20. If yes, who really initiated this discussion and why?
21. If you initiated the discussion, how did your spouse react to it and why (did he/she react the way that he/she did)?
22. What sorts of topics/areas were discussed regarding contraceptive use?
   - **Probes:** choice of methods, source of procurement, efficacy, cost etc.
23. When did you and your spouse start talking about contraception or desired family size with each other?
24. What were/are the different motivating factors/concerns for you/your spouse that forced you to talk about FP adoption with each other?
25. Did it ever happen that you intended to use any contraceptive but you did not discuss it with your husband, perceiving that he would disapprove of it? How did you perceive that?
26. What happened if there was a difference of opinion regarding the desired family size and contraceptive use?

27. How did you reach a decision regarding the use of contraceptives or family size: What is the role of the husband, the wife, and the mother-in-law?

28. How important is the role of your husband in making decisions regarding family size and FP/BS?

29. What would you do to avoid pregnancy if you do not want more children?

30. Would you like to start using any contraceptive method?

31. What would you do if your husband does not want to use FP?

32. Do you approve or disapprove of FP/BS? Why?

33. In your view, does your spouse approve or disapprove of FP/BS? Why?

34. In your view, if a woman approves of FP/BS and her husband does not, can she convince him to (allow her to) use contraceptives?

   • If yes, how (grounds of the arguments, time in process of communication)?

   • If not, why not?

35. (For women who never communicated with their husbands) Why did you never discuss family size and contraceptive use with your husband? What are the reasons that made you feel that it was not important (Probe for any social or cultural constraints)?
Role of interventions in shaping fertility behavior of men

1. Have you ever heard about an intervention in your area for men to educate or sensitize them about contraceptive use and family size (prompt only in FALAH districts)? The intervention included media campaigns, MGMs, and meetings with RLs so that they can include this topic in their addresses.

2. Did you/your husband share any ‘main’ message of these interventions with each other?

3. What is your own opinion on these interventions?

4. Do you think that through interventions focused on men, you/your husband:
   - Could obtain more information on FP methods?
   - Could initiate a discussion on FP?
   - Could become more supportive in using contraception?

5. Do you think that the intervention has changed your husband’s views about FP/BS, number of children, and future intention to use FP/BS? How?

6. What kind of intervention had the most positive affect?

7. Do you think that interventions for women (LHW, media) have helped you to communicate or convince your husband of FP adoption? How?

8. Do you think that interventions for men helped you to communicate or convince your husband of FP adoption? How?

9. In your view, what kind of intervention (men/women) had/can have the most positive affect in increasing FP adoption?

10. In your view, did these interventions result in a convergence between you and your spouse regarding reproductive intentions?
Appendix E: Focus Group Discussion Guidelines (Men)

Perceptions about FP, fertility intentions, and inter-spousal communication

1. What types of health facilities are available in your community?
2. How far are these health facilities from this location?
3. What types of health services are provided at these facilities/LHWs?
4. About how many (%) of the women and children go to avail these health services?
5. Is any LHWs posted at the facility?
6. Are FP services available at these facilities (particularly LHWs)?
7. Do you know what FP services are being provided at these facilities?
8. For what purpose do women use FP services: Limiting and/or spacing?
9. Do you/the men from your area approve of FP and BS or disapprove of it? (What are the) Reasons for the approval or disapproval?
10. In your view, what is an ideal size (in terms of the number of children) of a family? Why is this number ideal?
11. In your view, does a couple discuss contraceptive use and the number of children that they want to have, with one another? Ideally, when do they start this communication in their marital life?
12. What sorts of topics/areas are discussed regarding contraceptive usage?
   - **Probes:** choice of methods, source(s) to procure method(s), efficacy, cost etc.
13. Why is there generally a gap in communication between the husband and the wife regarding FP use in our society?
   - **Probes:** social norms, husband’s dominating status, etc.
14. What are the different motivating factors/concerns for men and women that force them to talk about FP adoption with their spouses?
15. Between a husband and a wife, who generally realizes earlier that contraceptives should be used (in order) to induce a gap between births? Why?
16. Does it ever happen that a wife intends to use any contraceptive but does not discuss it with her husband perceiving that he would disapprove of it? How does she perceive it to be like this?
17. What happens if there is a difference of opinion between a couple regarding the desired family size and contraceptive use?
18. How does a couple reach a decision regarding the use of contraceptives: What is the role of the husband, the wife, and the mother in-law?
19. What are the positives if the husband and wife have an agreement on contraceptive use, and what are the negatives if they disagree with one another?
Role of interventions in shaping the fertility behavior of men

1. Have you ever heard about an intervention in your area for men to educate or sensitize them about contraceptive use and family size (prompt only in FALAH districts)? The interventions included media campaigns, MGMs, and meetings with RLs so that they can include this topic in their addresses.

2. Do you remember the basic, or the ‘main’ message of these interventions and what is your opinion about these interventions?

3. Do you think that through interventions focused on men, they (the men):
   - Can obtain more information on FP methods?
   - Can initiate a discussion on FP with their wives?
   - Can be more supportive of their wives in using contraception?

4. Do you think that the intervention has changed your views about FP/BS, the number of children, and future intention to use FP/BS? How?

5. What kind of intervention had the most positive effect?

6. Do you think that interventions for women can make it easier for women to communicate with or convince their husbands of FP adoption? How?

7. Do you think that interventions for men can make it easier for women to communicate with or convince their husbands of FP adoption? How?

8. In your view, what kind of intervention (men/women) had/can have the most positive affect in increasing FP adoption?

9. In your view, can such interventions result in a convergence between a husband and a wife regarding reproductive intentions?
